An aspect that the RSA history brings out is one that is common to all countries in sub-Saharan Africa – that of selecting only tangible heritage (monuments, relics, archaeological, and paleontological remains, marked landscapes) for heritage expression through tourism. This was mostly the case in the 1970s as the excerpts from the 1970 *National Monument Council* (1970–1998) illustrate: "...Indeed, owing to this extreme youth of our culture in SA and the absence of folklore and traditions one finds in older countries, it is perhaps more necessary for us... to preserve the relics we have" (Van Riet 1941: 07). Intangible heritage (UNESCO 2003) in the form of folklore was not recognized as representative of heritage identity of the country.

However, after independence and into the present, the South African Heritage Resources Agency (SAHRA), under the National Heritage Resources Act No. 25 of 1999, aims to *redress past inequities* relating to identification, recognition, selection, and expression of heritage belonging to all forms of "communities" or "publics" in RSA by consciously *promoting* what officials refer to as: "...new and previously neglected research into our rich oral traditions and customs" (SAHRA annual report 2001: 03).

The once neglected research include material culture that attest to historical archaeologies of Bantu-speaking groups as well as cultural material pointing to interaction between Bantu and San cultures. These identities provide a balanced cultural identity that could be expressed through heritage tourism in the present.

Historical Background

Cultural heritage is an offshoot of the discipline of archaeology, from which heritage studies emanated in most European and American universities. Subsequently, cultural heritage tourism falls within the same category although there is reluctance by archaeologists, historians, and anthropologists to directly push the development of cultural heritage tourism due to a lack of knowledge on the subject of tourism in particular. On the other hand, cultural heritage tourism has been hijacked by business management departments, although there is very limited knowledge about conservation needs of cultural resources in these departments. Cultural heritage tourism influences values placed on cultural resources as it provides an interface between the sociocultural and the socioeconomic aspects.

The trend in the demand for cultural heritage tourism is common among a sector of tourists known as *ecotourists*. Ecotourism is travel that respects both the environment and the cultures being visited, with a keen attempt to contribute to the welfare of communities in touristic places. Therefore, in addition to wilderness and wildlife, ecotourists are looking for an interaction with host communities as a way to understand their history, archaeology, and overall culture.

Cultural heritage tourism as a subdiscipline of both the heritage studies and broader tourism has achieved very limited, if any, formal recognition and home in southern African disciplinary discourses and research. In almost all instances, it is adopted within a department in a haphazard rather than a planned manner.

Boxes 1 and 2 are case studies from Botswana and the Republic of South Africa, presented below, provide indicators to look out for in the process of developing a cultural heritage tourism package in southern Africa. Preliminary focus on theorization of several concepts in order to situate its development within sub-Saharan approaches toward identification, selection, interpretation, and presentation is necessary.

As already mentioned, cultural heritage tourism as a subdiscipline of cultural heritage studies is still at its infancy in southern Africa. Archaeology, the discipline within which heritage studies originated in Europe, is not public oriented in Africa, hence alienates other groups that are not of academic focus that could use archaeological products to develop cultural heritage tourism. The alienation of the discipline from the local people is due to technical approaches to archaeological heritage research that focuses on hardcore science approach and neglects to articulate archaeology as a medium between science and construction of social histories and identities.

Against this background, a development of tourism interpretation has to be aware of a basic framework guiding identification, selection, and choice of cultural heritage, anchored upon three main archaeological research approaches being the culture history (1950s), processual (1960s), and post-processual (1980s) approaches. To balance tourism interpretation of African histories, more research on the sociocultural and socioeconomic significance of material culture using alternative methodological approaches is required. Examples of alternative methodological approaches that are more relevant for African heritage contexts include research by scholars such as Cleere (1989), Alison Wylie (1993), Conkey and Gero (1991a), Kohl and Fawcett (1995), and Palmer (2009).

Key Issues/Current Debates

Issues surrounding development of cultural heritage tourism in southern Africa are several, but those that deserve a heightened attention are those that relate to the following:

(a) Processes and indicators for identification and selection of cultural heritage for tourism
(b) Conservation of cultural resources relative to the overall environment
(c) Mechanisms of sustainable production and consumption of cultural and heritage resources
(d) Processes that enable host communities to identify, select, and present their own heritage to the tourists

Boxes 1 and 2 present case studies that illuminate on issues (a) to (d) above. The presented scenarios on Botswana and the Republic of South Africa illustrate angles to be covered in order to exhaust hidden aspects that may influence a practitioner's point of departure when developing a tourism product. The angles include political, social, economic, communal, intellectual, historical, academic research, and others.

One of the key issues that dominate packaging and presentation of cultural heritage resources for tourism is the relationship between the resources and the various stakeholders. This is not unique to countries in southern Africa. In some parts of sub-Saharan Africa such as Kenya, a prolonged focus on prehistory or "early man" meant to create and project a national identity to the outside world (tourists) have had a negative effect of delaying development of local cultural heritage within the country (Schmidt and Patterson 1995). An added focus on safari tourism in the same country, as well as in most parts of southern Africa, provides yet another example of packaging a somewhat "neutral" and nationalistic heritage for outside tourists. These examples illustrate earlier approaches to packaging cultural heritage resources for tourism to influence tourist consumption. Further examples from other regions include the ". . .racial and imperialistic policies in archaeological research under the Nazis" (Arnold and Hassmann 1995: 73), during the Third Reich in Germany, as well as an example of the use of the history of the farming class in Denmark to create national identity (Kristiansen 1992). In all these cases, the relationship between archaeology, the state, and the local community affects communities' attitudes and perceptions toward a heritage which is consequently extended to the "tourist public" through tourism experience.

Another key aspect in the development of cultural heritage tourism is the need to engage local communities, an approach which emanates from a participatory approach principle of sustainable development (cf. Midgley 1986) within the broader conservation debate. As a starting point, heritage legislation (particularly national) is an indicator of a direction that a budding field such as heritage tourism is taking within a country as shown in Boxes 1 and 2 where the development of heritage legislation illuminates colonial aspects of heritage management that that have to be aligned to the present. Key basic questions that are brought out by the two case studies are:

What indicators are used to identify and select a particular heritage as significant?
What is selected? Why?
By whom is it selected and presented?

International Perspectives

International institutions that deal with cultural and heritage resources conservation are beginning to incorporate tourism into cultural resources management. However, a lot still needs to be done in coming up with tourism procedures that speak to cultural heritage tourism as opposed to tourism in general.

The United Nations (UN) has several institutions that are relevant to the development of cultural heritage tourism in southern Africa. The United Nations Educational, Scientific and Cultural Organization (UNESCO) and the United Nations World Tourism Organization (UNWTO) are two of the most relevant institutions in this regard. Other international institutions include the International Council on Museums and Sites (ICOMOS) and the World Commission on Environment and Development (WCED), otherwise known as the Brundtland Commission.

UNESCO's focus on world heritage in the 1970s added a conventional management approach to heritage which was later expanded from tangible (1972 Convention) to intangible (2003 Convention) cultural heritage. In 2008, UNESCO came up with a Sustainable Tourism Programme which is being augmented by the 2011 World Heritage and Sustainable Tourism Programme. Still within UNESCO, the 2005 Convention on the Protection and Promotion of the Diversity of Cultural Expressions that addresses policies and measures relating to conservation of cultural diversity and cultural expressions (www.unesco.org) is yet another convention that

augments cultural initiatives toward cultural heritage tourism development.

In addition to UNESCO, the International Council on Monuments and Sites (ICOMOS) provides insight on matters relating to cultural heritage resources management within which principles governing tourism applications on cultural sites are considered (www.icomos.org). In particular to tourism, ICOMOS adopted an "International Cultural Tourism Charter" in 1999, in which it is recognized that "Tourism promotion programmes should protect and enhance Natural and Cultural Heritage characteristics" (ICOMOS Tourism Charter, principle 6).

One other convention that supplements UNESCO and ICOMOS conservation measures is the 1971 Ramsar Convention on Wetlands (www.ramsar.org). In 2002, the convention secretariat, through its Culture Working Group, came up with Resolution VIII.19 on "Guiding principles for taking into account the cultural values of wetlands for the effective management of sites", followed in 2005 by the Resolution IX.21 on "Taking into account the cultural values of wetlands." All of these culminated into a 2009 document titled "The future of the WHC: Ramsar contribution," a bilateral cooperation between the international organizations.

Overlooking the implementation of conservation measures is the popular *sustainable development* framework initiated under the World Commission on Environment and Development (1987) model but with conservation guidelines that are compatible with both cultural and natural resources. The WCED's emphasis on development of conservation indicators provide for resources monitoring strategies to ensure that cultural resources are not vandalized nor depleted in a way that deprive future generations a chance to experience them. However production and consumption indicators for cultural and heritage resources are currently not available (Keitumetse 2005, 2009), although there are plenty of those for natural resources such as forests, wildlife, and others. Cultural heritage practitioners and associated professionals have to kick-start this process to ensure conservation of cultural heritage resources.

The ecotourism conservation model has brought attention to cultural heritage as a component of tourism in Africa.

With time, tourists are gradually developing interest in cultural landscapes where resident communities live in proximity to monuments and national parks of southern Africa. The realization is that "The unique selling point for destinations in developing countries is likely to be increasingly associated with the uniqueness of unusual cultures, as opposed to the physical environment. . ." (Burns 1995: 12). A framework similar to sustainable development (SD), where production and consumption indicators relating to cultural resources and applicable to sustainable heritage tourism are developed, is needed to achieve sustainable tourism using cultural heritage resources.

Future Directions

Cultural heritage tourism in southern Africa is growing at a very high rate. The concern however is that it is spearheaded by travel and tourism professionals that are not well versed and/or are not concerned much with conservation needs of cultural heritage resources such as archaeological heritage, museums, and social culture, community anthropology, and others. Due to its appeal to tourism commercial business, cultural heritage tourism is currently pursued within the commodification sectors at a superficial context fueled by the desperate need to diversify the tourism product. It is imperative that cultural specialists (archaeologists, anthropologists, and social scientists in general) and practitioners (local communities that host the culture and its heritage) take the responsibility to situate the direction of growth of cultural heritage tourism. This will enable a sustainable framework that recognizes conservation needs of cultural resources.

One direction that could guide the use of cultural heritage resources in tourism is to consider significant placement of cultural heritage resources within the sustainable development framework (cf. WCED 1987; Hall 1992;

Keitumetse 2005). Sustainable development emphasizes current use of resources in a way that ensures their continuity for future generations. The question is how can this be achieved?

A way forward may be to align conservation ideals of cultural heritage resources with the processes of sustainable development framework whereby production and consumption indicators specific to cultural resources are identified to enable monitoring of use in order to limit destruction. Currently, very few, if any, of these indicators exist for cultural and heritage resources, let alone a clear guidance on what constitutes cultural resources suitable for use in tourism. Preliminary research discourses have been attempted in this regard though at a very localized and limited level as evidenced in Keitumetse (2009) on "Ecotourism of Cultural Heritage Management."

At an operational level, eco-certification of tourism establishments is becoming popular within hotels, game lodges, camping areas, and game reserves. For example, the Botswana eco-certification system for ecotour standards as well as accommodation standards (Botswana Tourism Board 2009) is one such initiative whereby cultural aspects of tourism can be infused (cf. Keitumetse 2016c). Within such operational frameworks, once devised, indicators that support sustainable use of cultural heritage resources can be mainstreamed to enhance conservation of cultural heritage resources. For a detailed understanding of eco-certification, refer to Leslie (2001) on serviced accommodation and environmental performance, Sasidharan et al. (2002) on developing countries and eco-labels, Drumm and Moore (2002) on ecotourism development manual, and Botswana Tourism Organization (2010) on Botswana eco-certification grading. The equivalent of eco-certification program is necessary in cultural heritage tourism that takes place in protected areas such as world heritage sites that may be in danger due to large numbers of tourists. Keitumetse (2016c) articulates initiatives toward this approach.

Particular to southern Africa is the issue of community involvement. What is a community culture? How is a community culture identified in tourism setup and benefits? Who chooses community heritage for use in commercial endeavors? And many other topics that can be reflected upon.

Digital technology provides conservation opportunities that may reduce threat to cultural resources. Virtual exhibitions of sites in open-air museums as well as housed museums have potential to support future development of cultural heritage tourism in southern Africa.

At a scholarly level, cultural heritage studies is still lacking a theoretical framework within which subfields such as cultural heritage tourism could source guidance. Cultural heritage studies are still haphazardly placed in terms of theory and so is the implementation of cultural heritage tourism.

Amid all the opportunities however, it is important to acknowledge that the relationship between cultural resources and the commercial service that is tourism is impressionable, hence requires constant alignment.

Southern Africa: Historical Archaeology

Innocent Pikirayi
Faculty of Humanities, Department of Anthropology and Archaeology, University of Pretoria, Pretoria, South Africa

Introduction

Several trends and themes in the discipline of historical archaeology are apparent in southern Africa since the early 1990s. These include, and are not limited to, the study of African-European contact and interaction, the study of the emergence of the modern (post-1500) world, the study of the origins of modern historical identities, and the study of heritage and the recent and contemporary past. These trends and themes are not mutually exclusive but rather demonstrate considerable convergence and overlap with one another. They are largely influenced not only by an emerging postcolonial academic critique in a region where European colonization had a major impact on African societies but also by emerging global trends in archaeological theory.

Meanings and Approaches

While studies up to the early 1990s regarded historical archaeology as essentially the archaeological study of documented African societies primarily by Western sources (see, e.g., Pikirayi 1993), subsequently approaches take a radically different view (Hall et al. 1993). This is conditioned by problems arising from the dichotomization arising from our intellectual perceptions of human development, conveniently divided across much of Africa into traditional cultural stages of Stone Age, Iron Age, and the historical period. This approach, which perceives society as having a prehistory prior to history, compromises understanding of the past, largely negating cultural continuities which European colonialism attempted to disrupt after 1500 AD. A major constraint is the narrow time depth and limited spatial coverage of European sources and the exclusion of pre-European, oral histories from many, although not all, such studies. There is an increasing need toward accessing the "voiceless" through the study of their material culture, as these were underrepresented and often falsely represented in written texts (Reid and Lane 2004; Schmidt and Mrozowski 2013).

In southern Africa, European documentary sources have dominated studies in historical archaeology. European travelers', traders', and visitors' descriptions of the coast and inland regions date from the fifteenth century onward. Though limited in nature, Arabic sources refer to

the Indian Ocean coast and parts of the hinterland from the early tenth century. However, southern African scholars have not considered periods prior to the fifteenth century strictly as defining a historical period, and thus there is a divide around 1500 AD (see Swanepoel et al. 2008), when prehistory supposedly comes to an end. The use of "external" texts in framing African societies in this way has been questioned (Schmidt and Mrozowski 2013; Pikirayi 2013).

An alternative approach to historical archaeology in Africa comes from the use of "internal" sources, dominated mainly by oral traditions, local histories, and folklore, all of which constitute the primary means of preserving and passing on traditional information and knowledge systems. Oral traditions have been criticized for their narrow time depth, selective coverage of information, central focus on ruling dynasties, and narrow content verging on myth. The general perception by many historians is that they are less reliable than written, "external" sources. However, some African historians such as Beach (1994) have shown the usefulness of these "internal" sources, especially if approached more critically (see also Vansina 1985).

Into the Twenty-First Century

At the beginning of the present millennium, southern African historical archaeology focused on the study of African-European contact and interaction over the last 500 years, with particular emphasis on European expansion, modernization, and the relationship between colonialism and the formation of local identities (Pikirayi 2004; Swanepoel et al. 2008). A number of research themes developed from this, including the rise of merchant capital in Europe, the development of plantation economies in the Mediterranean, European arrival, and expansion into southern Africa post-1500 AD (Elphick and Giliomee 1980; Schrire 1988; 1992a, b; 1995; Schrire and Deacon 1989; Schrire et al. 1993). Gold prompted the Portuguese to outflank the trans-Saharan trade and the trade involving the Zimbabwe plateau and eastern Africa. The migration of plantation economies from the Mediterranean to the Atlantic and later the Indian oceans promoted trade in slaves, initially to the offshore islands and, subsequently, the Americas. This impacted southern African social formations, as new complex societies emerged in response to changed circumstances. Contacts were both beneficial and destructive to the parties concerned, although Europeans always wanted to manipulate them for maximum gain. Some societies resisted strongly for their survival, while others adapted to the colonial settings, manipulating them to their own advantage. This process continued until the late nineteenth century following renewed European colonization of the region.

These developments constitute historical archaeology as an archaeological study of the origins of the modern world (Hall and Silliman 2006), dominated by European colonization. However, historical archaeology was not framed primarily in terms of external agents which impact on indigenous African societies in some of the ways already described. Rather, studies on the origins of modernity sought to understand the colonization process in terms of agency – interpreting the "the absent present" behind the artifacts – as a force driving the historical process. (Pikirayi 2009).

Another dominant theme which emerged in southern African historical archaeology during the time was the origins of modern identities. This approach demonstrated that modernity should not be framed in European terms but, rather, conditioned by deep, long-term histories severely punctuated by colonization. The disciplinary identity of historical archaeology, in this regard, went beyond the last five centuries, as some contributors in Swanepoel et al. (2008) demonstrate. Southern African societies do show remarkable cultural continuities going beyond 1500 AD. The origins of the Nguni and Sotho Tswana are examples (Huffman 2004). Other studies have managed to re-interrogate the nature of cultural and other identities presented in written texts as historical. The study of the Mutapa state in northern Zimbabwe (Pikirayi 2009) shows considerable dualities in archaeological sites often identified in written

texts essentially as Portuguese trading fortifications. Such studies have also demonstrated the need to conduct archaeological investigations for situations where primacy is given to either written or oral texts (see Parkington and Cronin 1979; Pikirayi 1997, 1999; Pikirayi and Pwiti 1999). Such approaches were extremely helpful as they invoked the element of agency, echoing earlier studies on the foundations of Cape Town (Abrahams 1993; Hall 1992, 1993, 1994, 1999; Hall and Markell 1993; Hall et al. 1993), including consideration of the enslaved (e.g., Markell et al. 1995; Cox et al. 2001). Other examples where material and other identities were explored include the expansion of the European "frontier" into the hinterland, and how encounters were negotiated with indigenous people at points of contact (Swanepoel et al. 2008), and the variable responses of different African communities to the expansion on Christianity and the work of nonconformist missions (e.g., Lane 1999; Reid et al. 1997).

Historical archaeology also focused on cultural landscapes and documenting memories imprinted therein. Some of these memories include, but are not limited to, warfare, social formation, movement and migrations, and settlement. Examples include studies of the Ndwandwe kingdom, the Swazi origins, and the *mfecane*, the South African war of 1899–1902, the history of the origins of major urban centers such as Pretoria and Cape Town, and industrialization. In this way, historical archaeology may be regarded as a study of contemporary history or heritage, which directly affects people's lives, and this represents living histories. Thus such approaches dealt with "the past in the present" (Orser and Fagan 1995), a living archaeology affected by contemporary issues such as politics and economics. Here, archaeological research reclaims pasts that may have been denied in one way or the other, given the region's highly checkered colonial histories. South Africa, which identified itself as the "Rainbow Nation" post-1994, in reference to the diversity of its peoples and cultures, has successfully integrated archaeology into the education curriculum, recognizing the deep historical roots, where current complex politics derive from many centuries of cooperation and conflict between Europeans and Africans.

Emerging Trends

A workshop on historical archaeology in southern Africa, focusing on the theme "Local Sites/Global Intersections" and held at the University of South Africa (UNISA) in October 2014, set the trend and way forward for the region. Several themes emerged, which went beyond material culture studies of sites categorized as belonging to the "historical period," and include engaging with scholars elsewhere across the globe, material culture identities, and early Christian missionary activity. The conference engaged with scholars from Australia and Europe to understand better issues of indigeneity, identity formation, the changing nature of patriarchy during the nineteenth century as new opportunities emerged, and European settlement and colonialization of southern Africa. Discussions around this theme realized how limited dualisms were, e.g., labelling of artifacts as indigenous/European may shape the way in which we interpret such objects, when we may be looking at the results or outcomes of entanglement and bricolage. Not very much has been studied in terms of resilience and capacity of indigenous/local populations. Beyond the identification of material culture in contexts considered historical, there were discussions on collections management, care, and access, including human remains. This brought historical archaeologists into the domain of cultural heritage management, which is legislative driven as much as it is highly politicized. Some papers covered topics on the collapse of settlement systems; the spread of maize, ivory, and other forms of trade; and the dynamics of, and on, the moving colonial and other frontiers.

A dominant theme that is also part of global conversations emphasizes the profoundly material dimensions of early Christian missionary activity. The objective is to understand the role of missionaries, whose influence is global in nature, and very

much a significant component of European expansion, in the remaking of the modern world. Beyond this, missionaries have transformed the region in so many ways tangible and intangible and, as such, are critical role-players in narratives of modernity and modernization. The global networks of exchange established by missionary organizations, the materials that circulated through these, and the effects these exchanges had in many different parts of the world, beyond Europe, were highly transformational. Researchers are now investigating the missionary landscapes by exploring missionary architecture; mission sites; missionary education institutions; missionary impact in the region; missionary material culture, especially the printed word and the archival record that goes with it; modes of travel and transport; and missionary heritage such as museums and memorials and the agency associated with it.

A session in the Association of Southern African Professional Archaeologists (ASAPA) biennial meeting held at the University of Pretoria in July 2017 highlighted the use of high-tech aerial surveys to understand the proto-urban landscape of southern Africa. This involved the use of LiDAR to make population estimates that lived in some of the large seventeenth- to nineteenth-century Sotho-Tswana stone-walled settlements, as well as their inter- and intra-settlement organizations through time and space. These studies recognize that large aggregations of people in urban settings have profound sociopolitical and environmental implications. There is also a loss of some of these settlements due to modern urban sprawl, as is the case with the stone-walled settlements south of Johannesburg.

An interesting research conducted on the Mpumalanga Escarpment of South Africa integrates archaeology with the oral histories of the Koni people and early European expansion and subsequent settlement in the area to understand stone-walled terraces, homesteads, footpaths, fortifications, and other structures, covering more than 10,000 km^2 (Delius et al. 2015). This research can be contextualized in a continent-wide focus on the development of "islands of intensive agriculture" (Widgren and Sutton 2004) in broadly similar geographical locations during the last 500 years, in response to the impact of the Little Ice Age (Hannaford. et al. 2014; Pikirayi 2016).

Another interesting development is closely linked to community and public archaeology and involves to '"listening" to oral accounts relating to specific places such as Great Zimbabwe. The development and demise of Great Zimbabwe are poorly understood because of the lack of appreciation of local and regional histories of the southern Zimbabwe plateau, post-1500 AD (Pikirayi 2006). Paying attention to some of these extant histories and living narratives is key to understanding developments around Great Zimbabwe from 1500 AD onward. These histories and narratives are connected with the adjacent landscape and regions beyond, revealing interesting local dynamics that connect Great Zimbabwe with developments in distant parts of the Zimbabwe plateau (Pikirayi 2017).

Conclusion

Southern African historical archaeology is an emerging discipline. Researchers involved realize that "everything is history," following the problematization of terms such as prehistory, precontact, and colonial. They see the need to widen the concept and scope of the discipline beyond the narrow, founding framework of historical archaeology being the archaeology of European colonial expansion. There is also the recognition that the integrity of the archive is central to the interplay between evidence and interpretation and in moving through contested concepts of the past. As such, adequate attention must be paid toward data collection and documentation since archaeology is a discipline that destroys in the process of discovery. Missions and other themes are critical in understanding frontiers, which are rich with cultural and other meanings, as well as material culture identities. Historical archaeology should play a more distinctive methodology in adding toward these meanings.

Archaeology can help better inform the history of southern Africa, since it is a vital source of evidence. Such history is critical to

understand the origins of the present. Challenges remain in terms of developing methodologies and theoretical frames, more critical being what it means to do archaeology in a context that is also informed by other sources – oral histories, written accounts, oral traditions, memories, etc. Scholars must also engage with the historical archaeologists from other regions of the world. A major problem facing North American approaches to historical archaeology, for example, is the exclusionary manner in which the discipline is framed. By confining historical archaeology to the era of capitalism and colonialism, the indigenous histories of many areas of the globe including Africa are of no interest to such an intellectual agenda. If we practice an historical archaeology that only valorizes the colonial experience, then we must explain what happens to history making that engaged cultures in the precapitalist and premodern era.

Southern Africa: Origins and Development of Agriculture

Innocent Pikirayi
Faculty of Humanities, Department of Anthropology and Archaeology, University of Pretoria, Pretoria, South Africa

Introduction

Some 2500 years ago in southern Africa – the subcontinent of Africa subsuming the basins of Kunene, Okavango, Zambezi, Kafue, Luangwa and Shire rivers, and Lake Malawi and all the regions to the south of these – foragers were drawn toward a process by which greater control over plants and animals gave rise to domestic forms. Gradually, some of these foragers became involved in metal production. These developments ushered in significant social, cultural, economic, ideological, and political changes on the societies involved. Most of the evidence for farming comes from archaeology through actual remains of cultivated plants and domestic animals and artistic representations of the latter in rock paintings or engravings. Although direct archaeological evidence remains poor due to the limited number of samples directly subjected to scientific analyses, a key factor remains the preservation of the evidence itself. While the biological evidence suggests that the process of animal and crop domestication was introduced from elsewhere, it appears the inhabitants of the subcontinent

continued to exercise greater, though not full, control of wild resources, a process which required no domestication. This may explain the continued reliance of both wild and plant resources, as the subcontinent's biomes allowed such interaction to take place.

Key Issues/Current Debates/Future Directions/Examples

Archaeological and Linguistic Background

Up to and until about 1500 years ago, the inhabitants of southern Africa were largely stone-using hunter-gatherers and most probably the ancestors of the modern San and Khoe (Mitchell 2002). Some 2000–2500 years ago, some of these hunter-gatherers became cattle and sheep herders. Archaeological evidence attesting to their presence in the region has been found in what is now southern Angola, Namibia, Botswana, and the Northern and the Western Cape regions of South Africa (Sadir 2013). They also made pottery, with some scholars suggesting they could have ushered in a form of "pastoral Neolithic" comparable to that from the more northerly and eastern parts of the African continent. However, this interpretation remains debatable (see, e.g., Robertshaw 2012; Russell et al. 2014). What is interesting though is the appearance of domestic sheep in the Western Cape region more than 2000 years ago, and how they were introduced into the region, most probably from eastern Africa, remains unresolved.

Subsistence practices directly associated with farming seem to have gathered momentum during the first and second centuries CE (Phillipson 2005). Communities linked to these developments cultivated millets, sorghum, lentils, melons, kept cattle, sheep, or goats. Initially, the farmers did not fundamentally change the subsistence patterns of the autochthonous communities. However, they were to leave their mark on the southern African landscape through pottery-making traditions that were so distinct that some Iron Age archaeologists have equated them to early forms of ethnic entities (Huffman 1989, 2007). Archaeological sites of the Chifumbaze complex or tradition, also referred to as Early Iron Age or Early Farming Community sites, are directly attributed to this development. The spatial pattern points initially to a gradual expansion of the farming population in the subcontinent (Vansina 1994/1995, 1989), resulting in substantial village settlements whose inhabitants also specialized in the production of metal, mainly iron. It remains unclear whether these farmers dispersed from the northerly part of the African continent or the knowledge reached the southern African herders and hunter-gatherers, the latter representing an internal transformation within such communities, moving toward a sedentary subsistence lifestyle. Linguistically, they are identified with the ancestors of Bantu speakers, who populate the region today (Huffman and Herbert 1994/1995; Ehret 2001), suggesting that the dispersal of ceramic traditions associated with early farmers correlates with the spread Bantu languages.

Physiography of Southern Africa

The subcontinent of southern Africa is made up of a number of biomes ranging from extreme desert to the west, to savannah in the east, sub-equatorial woodlands to the north, and temperate zones further south (Rutherford and Westfall 1994; Rutherford et al. 2006). The eastern half of the region is summer rainfall area, with the savannah biome the largest, covering over 45% of the area, characterized by open grassland and woodlands. Brachystegia and acacia are the dominant species. Altitude ranges from sea level to over 2000 m, where montane forest grows. Summer rainfall ranges from 200 to 1000 mm per annum. The region also has almost every major geological and soil type contained in it.

It is in these biomes that a wide range of plant and animal foods exist, both wild and domestic; these were at the disposal of the hunter-gatherers, herders, and farmers during the last two millennia or slightly more. Specifically, the savannah biome is home to seasonal forest fires and grazing which is ideal for wild animals, cattle, sheep, and goats, though the latter are highly tolerant of drier, hotter, and lower-lying altitudes (see, e.g., Vogel 1986; Hannaford et al. 2014).

Intensification of Farming

The intensification of crop cultivation must have started in the fifth century CE, with the expansion of farming communities in much of the southern African region. The region also witnessed gradual but significant transformations which shaped the character of early farmers. The second half of the first millennium CE saw the region opening up to the Indian Ocean trade, gold mining, and exploitation of wild animals such as elephants for ivory. This triggered economic specialization, with the society becoming differentiated following the development of chiefdoms and states. The middle Limpopo valley witnessed some of these developments at Schroda, Ratho, Bambandyanalo, Mmamagwe, and Mapungubwe, and there are indications that much of the Shashe-Limpopo experienced similar developments, as suggested by archaeological evidence associated with the Zhizo/Toutswe (CE 700–1300) and Leopard's Kopje (CE 900–1500) tradition sites in Western Zimbabwe and adjacent eastern Botswana.

A significant development from the late first millennium to the early second millennium CE is the increase in the number of cattle. This development is particularly notable within the Toutswe and Leopard's Kopje traditions. Toutswe sites show a definite hierarchy, with large settlements on the tops of hills being occupied for up to 300 years or more and smaller villages and homesteads scattered around near water sources and grazing. Well-investigated sites include Toutswemogala, Bosutswe, and Shoshong, and these could have been at the helm of chiefdom societies that existed in what is now eastern Botswana and trading with the Indian Ocean coast. These seem to have lost this trade to villages and towns now attributed to the Leopard's Kopje tradition, clustered further east in the middle Limpopo and Shashe river basins, and who also kept substantial cattle herds, as attested by large middens of vitrified dung located on the central parts of their settlements. One of these centers, Mapungubwe, developed a fully fledged state society during the thirteenth century (Huffman 2007).

The need for storage of agricultural produce becomes apparent, as attested by grain bins on sites associated with the Leopard's Kopje tradition. The state societies at Mapungubwe (CE 1100–1300) and Great Zimbabwe (CE 1200–1600) evidently became dependent on a rich agricultural hinterland to support their ruling elites and craft specialists, as well as large towns with a burgeoning population, all of which needed food. Storage was also an added insurance especially in times of droughts or periods of prolonged aridity, given the fragility of the savannah biomes in relation to global weather systems. Storage was also necessary during conflict situations, as later historically documented events show.

The Introduction of Maize

Maize, *Zea mays*, was introduced in Africa in the 1500s following the continent's contacts with the Atlantic world, the Americas – a process triggered by the Columbus voyages and Portuguese seafaring activities and the slave trade (McCann 2005). Since then, it has become one of the most dominant food crops on the continent. Maize is rich in vitamins, is a carbohydrate, and also contains essential minerals and protein. It is also a digestive, containing dietary fiber and calories. No doubt, given its origins in Central America, its cultivation was easier compared to that of sorghum and carried significantly higher yields. Maize seems to have displaced sorghum and millets in medium to high rainfall regions of southern Africa. Its impact in southern Africa was huge, as it increasingly became a staple for so many societies, but sometimes with negative consequences. A number of events associated with the Portuguese in Western and south-central Africa, during the sixteenth and seventeenth centuries, and the development of state formation among the Nguni in southeastern Africa followed by the migrations of the first half of the nineteenth century may be linked to the increased adoption as well as failure of maize due to climate fluctuations (Pikirayi 2016).

Issues and Debates

Several topics require answers when discussing the origins of agriculture in southern Africa. The first issue is whether the region may have

experienced earlier forms of food production among stone-using hunter-gatherers and herder-herders as opposed to the Iron Age farmers as is widely thought. Evidence demonstrating more direct connections with eastern Africa and the southerly parts of the Sahara is crucial in this regard. A potential area of study is the assessment of both domestic and wild prototypes, if any, in southern Africa, to determine why there is a limited range of domestic animals and plants, given the abundance of wild fauna and flora. Was domestication really necessary in this case? A third issue is the role of climate change on domestication of both plants and animals, and human subsistence patterns, given the known shifts from hunting to farming and back. For the more recent periods, it would also be interesting to assess the impact of the introduction of maize on southern African societies. Some of the major population shifts triggered by environmental stress and human conflict are speculatively linked with the introduction of maize on the subcontinent. The only challenge is the limited oral histories with direct references to southern African hinterland societies that may provide crucial testimony to this; otherwise, all the answers have to come from archaeology.

State of Knowledge and Current Debate

Introduction

The "Middle Stone Age" (MSA) is a temporal stage term used to describe sub-Saharan assemblages of the late Middle and Late Pleistocene. It was originally introduced by South African pioneer archaeologists Goodwin and Van Riet Lowe in 1929 to describe stone tool assemblages technologically distinct from those of the Early Stone Age (ESA) and Later Stone Age (LSA) periods. At that time it referred to assemblages in which convergent flaking on prepared cores was used to produce unretouched and retouched pointed flakes with faceted platforms. It is now known that the Middle Stone Age involves a much wider range of technological and typological variability, but the term still has currency as a historical and technological stage division. There is however no consensus on the definition of the Middle Stone Age (Wadley 2015), and transitions and differences between the ESA, MSA, and LSA are not clear cut. The Mode system, created by Clark in 1969 (Graham Clarke), is an alternative way to describe Paleolithic variability in terms of key innovations independent of temporal association. Modes 2–5 are associated with the Middle Stone Age with Mode 2 referring to bifacially worked tools such as hand axes and cleavers (▶ Handaxes and Biface Technology), Mode 3 to flake tools produced from prepared cores (Levallois), and Mode 4 to "punch-struck" blades sometimes retouched into various specialized tool types (Backed Geometrics). Mode 5 assemblages contain microlithic components of composite tools, often backed or retouched. "Modes" may be useful for describing key lithic innovations but have little further explanatory significance (Shea 2011). In Southern and East Africa, the first typical Middle Stone Age or Mode 3 elements emerge some time before the Middle Pleistocene (~430 kya–127 kya). The transition between the Early and Middle Stone Age was an extended process, and Acheulean and Middle Stone Age assemblages overlap in time. In Southern Africa the most recent Acheulean elements occur between 125 and 300 kya at Duinefontein 2 (Klein 2009), broadly the same time range as in East Africa where the youngest Acheulean artefacts are from the surface at Herto dating to around 160 kya and from Abdur, Eritrea, where 125 kya in situ hand axes occur (Tryon and Faith 2013). In both Southern and East Africa, the earliest Middle Stone Age assemblages without hand axes and picks are found around 280 kya, at interior sites like Florisbad, Kathu Pan, and Haaskraal in the former and Gademotta in the latter region (Wurz 2013; Tryon and Faith 2013; Bousman and Brink in press) (Fig. 1).

Southern Africa encompasses the area south of the Zambezi and the Kunene rivers and incorporates the countries discussed here, mainly South Africa, Namibia, Botswana, Zimbabwe, and Lesotho, but also Southern Mozambique and Swaziland. A wide variety of ecological zones and habitats occur in the vast Southern African region and includes savannah, arid and semiarid, grassland, and coastal environments. The coastal areas from the Cape contain a number of caves with extensive stratified deposits, indicating that between ~160 and 50 kya this area, with its high biodiversity and predictable resources, was favored in the MSA. The southern Cape coast may have been a refugium in Marine Isotope Stage (MIS) 6 (Marean et al. 2014) and thus

Southern and East African Middle Stone Age: Geography and Culture, Fig. 1 Map of sites in Southern and East Africa mentioned in the text

could have played an important role in the evolution of the human phenotype or evolution of typical morphology, development, and behaviors (▶ Human Evolution: Theory and Progress). Similar productive environments associated with significant water bodies such as lakes or pans also occurred in the interior of South Africa during MIS 6 when sites like Florisbad and those associated with the early Pietersburg technocomplex were inhabited. The Southern African interior is dominated by the Kalahari Basin, the largest continuous sea sand in the world (Burrough 2016). It

S

covers the area north of the Orange River and encompasses large parts of Angola, Botswana, Zimbabwe, Zambia, and Namibia. Predictability of water sources such as the large lakes found in the Kalahari would have been a significant factor in influencing occupation patterns and cultural adaptive patterns (Burrough 2016). The MSA of Tanzania, Kenya, and Ethiopia is most intensively researched in East Africa and forms the focus of this review, but cursory reference is also made to other sites in the region. Rifting has caused the relatively small Eastern African area to be divided into small localized habitats ranging from very high escarpments to lake basins. This high habitat heterogeneity increased the availability of refugia throughout the Quaternary and consequently might have influenced the development of modern humans (Lahr and Foley 2016).

The MSA is covered by Marine Isotope Stages (MIS) 13-1. For the past 450,000 years, the extremes between cold and warm phases became more pronounced, and the warm interglacials became shorter than in earlier time periods. Marine and ice cores from the northern hemisphere provide information on global climatic changes of the past, whereas southern hemispheric changes reflect in the Dome C ice record from Antarctica. On a general level, terrestrial and marine records suggest that Africa experienced increasing aridity during cold glacial phases and wetter conditions during interglacials. It is further evident that brief interstadials (Dansgaard-Oeschger events) influenced climate for the last ~100,000 years. These rapid warming periods took place on a decadal scale and were followed by gradual cooling periods. Contemporaneous but less intense and rapid change is reflected in the Antarctic ice record. The Heinrich events that occurred after ~70 kya in the North Atlantic and resulted in cold dry stadials had an uncertain impact in sub-Saharan Africa (Barham and Mitchell 2008). There is no deterministic cause and effect relationship between climate and evolutionary change, but climate influences environmental conditions and populations' evolutionary context and in this way play a role in shaping human adaptive patterns (Lahr 2016). The relationship between climatic and environmental change is nuanced and context specific and regions within Africa are differently influenced by climatic change (Blome et al. 2012). Overarching climatic theories are less useful to understand past population dynamics as it is influenced by regional environmental variability and especially the availability and predictability of surface water (Burrough 2016). Data from multiple regional terrestrial proxies that indicate changes on a regional scale are needed to productively explore the effect of past climatic and environmental change on Southern and East African Middle Stone Age populations ("▶ Environmental Reconstruction in Archaeological Science," "▶ Geoarchaeology," "Climate Studies").

Modern Human Origins

Homo sapiens, also informally referred to as "anatomically modern humans" (AMH), developed as part of a protracted process of more than 250,000 years in Africa (Lahr and Foley 2016). Molecular genetic data are crucial for exploring the origins of *Homo sapiens* (▶ DNA and Skeletal Analysis in Bioarchaeology and Human Osteology). According to genome-wide autosomal DNA, the Y chromosome, and mitochondrial DNA (mtDNA), extant African populations have the highest levels of genetic variation (Soares et al. 2016), indicating an African origin for all modern humans. It is probable that fossil evidence for early *Homo sapiens* would be found in the African Middle Pleistocene fossil record (Stringer 2016). There is debate, however, on exactly where in Africa the first modern humans developed and how populations dispersed. AMH likely did not descend from a single group of people from a specific area and time period but developed from a network of groups that interacted with each other (Soares et al. 2016). Southern Africa presents evidence for particularly early human groups. The analyses of the complete genome of a 2000-year-old boy from Ballito Bay, from the KwaZulu-Natal coast, indicate that the population divergence time between him and 42 other groups dates to beyond 260 kya (Schlebusch et al. 2017). mtDNA and genome-wide data further suggest that such early Southern African groups, ancestral to the Khoe-San people,

were isolated in this region prior to 140 kya. The variability in two basal haplogroups, or clades that represent clusters of lineages that descend from a common ancestor in the mtDNA tree, L0 and L1, shows that by 140 kya two groups of modern humans lived in Africa. The L0 haplogroup has a Southern African origin and the related L1'6 haplogroup a Central or Eastern African origin. The distribution of haplogroup L0 further implies gene flow from Southern Africa to Eastern Africa between ca 130 and 70 kya. The migration out of Africa by modern humans is a different event and concerned the expansion of, for example, haplogroup L3 ca. 60–70 kya (Soares et al. 2016).

The fossil record relevant to the evolution of humans is sparse and not well dated. Some regions, such as the Kalahari, are not represented at all (Robbins et al. 2016). The *Homo sapiens* hypodigm, or sample available for a specific taxon, is complex and highly variable. Although there is debate on precisely which traits constitute anatomical modernity, uniquely *Homo sapiens*-derived traits include a more globular shape of the cranial vault and a reduction in the projection and size of the face, as well as a chin or mental eminence (Lahr and Foley 2016). Morphologically distinct populations probably co-existed in Africa during the early phases of modern human origins (Stringer 2016). An early group with relatively more robust features from East Africa is from Eliye Springs and Ngaloba (Stringer 2016, "▶ Fossil Records of Early Modern Humans"). In Southern Africa *Homo helmei* from Florisbad, South Africa, dating ~260 kya is part of the early archaic *Homo sapiens* clade (Stringer 2016). A tooth with archaic characteristics from Lincoln Cave Sterkfontein possibly belongs to the same group (Wadley 2015).

The fossil remains from Omo and Herto, Ethiopia, represent another cluster within the *Homo sapiens* hypodigm (Tryon and Faith 2013). The Omo I calvarium, from Kyamoya's Hominid Site (KHS) in the Kibish Formation, southern Ethiopia, dates to ~195 kya, whereas the four individuals from the Herto member of the Bouri Formation are associated with ages ranging of between 160 and 154 kya. These remains have long been considered the earliest members of *Homo sapiens*, but they reflect many archaic traits. Archaic traits are also present in Late Pleistocene *Homo sapiens* in East Africa that include fossils from, for example, Aduma, Porc Epic, and Mumba (McBrearty and Brooks 2000). No human fossils seem to occur between MIS 4 and MIS 3 (Lahr and Foley 2016), and archaic elements can be found into the Late Pleistocene (Stringer 2016).

The earliest representatives of anatomically modern *Homo sapiens* in Southern Africa come from Klasies River (Klasies River Mouth and Related Sites) where a relative large collection of cranial and postcranial fossils have been found (Grine 2016). Two maxillary fragments that date to ~120 kya are the oldest hominins from the site, with the majority of the fossils dating to between ~100 and 80 kya. A few also relates to MIS 4. These fossils show cut marks and burning, consistent with cannibalistic practices (Deacon and Deacon 1999). Border Cave provides an enigmatic collection of human fossils, with the earliest reliably dated individual dating to ~70 kya (Wadley 2015). Fossils with no particular diagnostic traits, all probably post-dating 80 kya, occur at Cape sites such as Klipdrift Rock Shelter, Blombos Cave (Blombos), Pinnacle Point (Cave at Pinnacle Point, S Africa), Diepkloof Rock Shelter, Die Kelders, Hoedjiespunt, and at inland sites further north at Plovers Lake and Bushman Rock Shelter (Wadley 2015). The infant from Border Cave dating to 74 ± 4 BP, excavated from the base of the Howiesons Poort, is of particular interest as it is considered to be the first burial of a modern human recorded in Africa. The burial is associated with a perforated *Conus* shell (d'Errico and Backwell 2016). The 36 kya Hofmeyr skull is distinct from other contemporaneous humans in Africa, underscoring the diversity within the later Pleistocene modern human populations in the continent (Grine 2016).

Middle Stone Age Lithic Variability

Middle Stone Age stone artefacts provide the most ubiquitous clues to the behavior and population dynamics of early humans in Africa, relating to adaptive changes over an extended period of time involving different populations. MSA groups frequently used Levallois or prepared

core technology (McBrearty and Brooks 2000; Wurz 2013; Tryon and Faith 2013). The Levallois method originated within the ESA. In Southern Africa older prepared cores are associated with the million year old Victoria West industry at the site of Canteen Kopje, Northern Cape, in which large preferential flakes were retouched into Acheulean hand axes (▶ Acheulean Industrial Complex). Prepared or Levallois cores are designed to produce preformed flake blanks with little or no further shaping by retouch (▶ Lithic Technology, Paleolithic). In Levallois technology the core is conceived of as two opposing volumes that play different roles in the production process. The non-production volume serves as striking platform, and "end products" or "intended products" are only removed from the upper surface that is methodically prepared. The convexities created by the preparation guide the fracture path during knapping and design the shape of the removed flakes. In the preferential method, a single blade, flake, or point is removed before repreparation, and in the recurrent method, a series of products are knapped before repreparation. Preparatory and predesigned flakes can be removed unidirectionally, bidirectionally, or centripetally. The Nubian type 1 method is a specific variant of Levallois technology in which the convexities of the production surface are prepared by removing two elongated flakes from the distal end of the core (Tryon and Faith 2013). This technology is frequently used to follow connections between populations that moved between the north Nile Valley and parts of the Arabian Peninsula during Out of Africa events. Nubian type 1 technology also occurs in the MSA of East Africa, at or near sites of the Nile drainage basin, at K'one and Aduma in Ethiopia, and the Rusinga Island in Kenya indicating that this variant was widespread (Tryon and Faith 2013). That the Nubian type 1 technology is found at sites like Mertenhof and Uitspankraal 7 in southwestern South Africa suggests that similar types of technologies do not always indicate diffusion or dispersal but rather technological convergence (Will et al. 2015).

MSA knappers were competent and resourceful technologists and reduced cores in a variety of ways, depending on the raw material and types of flakes needed. They used discoidal technology to produce flakes through alternate flaking from both sides of (usually) a cobble blank. Single- and multiple-platform core technology, where one or more edges of a core were used as striking platforms without preparation, and bipolar technology in which a core is flaked on an anvil were also utilized. Blade and bladelet production was an established part of MSA technology that occurred already around 500 kya in Southern and East Africa (Tryon and Faith 2013; Wilkins and Chazan 2012). The blade technologies encompass a wide range of approaches, including volumetric, Hummal, and adapted Levallois. Truncated faceted pieces, used for the production of small blades, have been reported from East Africa (Tryon and Faith 2013) but not Southern Africa.

Goodwin and Van Riet Lowe considered convergent flakes or points with faceted platforms especially different types of worked points as the "typical implement" of the Middle Stone Age of Southern Africa (Wurz 2013). Almost a century of research has shown that unretouched, unifacial, and bifacial points, produced by a variety of methods, are indeed characteristic of the MSA of both Southern and Eastern Africa. There are stylistic differences in the shape and degree of modification of the points, and this reflects regional differences, as JD Clark suggested (McBrearty and Brooks 2000). The analysis of the technological procedures used in point production in addition to the morphological aspects would allow recognizing further regional variability (Douze and Delagnes 2016). In addition to retouched and unretouched convergent pieces or points with faceted platforms, flake and blade blanks and various types of preparatory products with many different platform types also occur. The retouched element in the MSA is small, and notched and denticulated pieces, unifacial and bifacial points, scrapers, and backed artefacts occur in low frequencies. Backed artefacts and retouched points are frequently used as culture stratigraphic markers, especially when adequate dating is not available. A variety of methods, including radiocarbon dating, optically stimulated luminescence (OSL), thermoluminescence, electron spin resonance (ESR), amino acid

racemisation (AAR), and U-series dating, are applied to determine cultural change through time in the MSA. The temporal framework in Southern Africa is better established than in East Africa where change through time largely relates to bedrock geology dated through, for example, $^{40}Ar/^{39}Ar$ dating of tuffs. The MSA sequence of Southern Africa is consequently discussed in more detail than that of East Africa.

The Middle Stone Age Lithic Sequence From Southern Africa

Most of the recent information on the MSA sequence in Southern Africa comes from long sequence sites in South Africa and Lesotho and relates to MIS 6–2 (Lombard et al. 2012). The earlier phases are represented by open-air sites, especially in the northern areas of Southern Africa, where the Sangoan and Lupemban industries document the transition to the MSA. The Sangoan is characterized by core axes and picks, blades, and many scrapers. The Lupemban also contains core axes and picks, in addition to its marker tools, large elongated bifacially retouched lanceolate points > 10 cm long, and backed blades (Barham and Mitchell 2008). These industries were once considered to be regionally restricted phenomena only present in the Pleistocene forested areas of Central Africa. Kalambo Falls in Zambia, initially excavated by J.D. Clark (▶ Clark, John Desmond) and now investigated by L. Barham, is an important stratified site where both industries occur. Sites with Sangoan-like picks and core axes also occur in Namibia and the Matopos region from Zimbabwe (McBrearty and Brooks 2000). Kuman and colleagues further describe Sangoan assemblages from open-air sites in the Mapungubwe National Park and surrounding farms situated on the border with Zimbabwe and Botswana. These are the oldest archaeological sites known from this area and contain small bifaces and picks, cleaver-like tools, denticulates, and denticulated scrapers, as well as prepared cores with Levallois-like traits (Wadley 2015).

The Fauresmith industry from South Africa contains small ovate finely made hand axes, frequently associated with Levallois cores, large blades, and points (Deacon and Deacon 1999). Well-known Fauresmith assemblages, with ages of between 600 and 300 kya, are from Northern Cape open-air sites such as Rooidam, Kathu Pan, and Bundu Farm with Wonderwerk Cave the only cave site occupied (Watts et al. 2016). In the Kathu Pan 1 assemblage from the 500 kya stratum 4a (Wilkins and Chazan 2012), hard hammer percussion was used to remove blades from methodically centripetally prepared cores. Numerous unifacial points and unretouched triangular flakes and blades also occur. The pointed flakes carry diagnostic impact fractures, and through experimentation using the same type of raw material, banded ironstone, Wilkins et al. (2012) show, not uncontroversially so, that they were hafted and used in projectile weapons such as spears.

In South Africa and Lesotho, MSA assemblages with ages of between ~300 and 130 kya are known as the Early Middle Stone Age (EMSA). Generally, assemblages from the EMSA are small and await detailed description, but they are associated with low frequencies of retouched tools and blades and flakes sometimes produced with the Levallois technique. At Kathu Pan, Haaskraal, and Florisbad in the interior, the EMSA are associated with ages of between 290 and 260 kya (Bousman and Brink in press). The Florisbad ~280 kya assemblage is dominated by small broad flakes from multiple-platform cores with little evidence of Levallois technology or points. The EMSA is perhaps best represented by the Pietersburg technocomplex, a regional phenomenon restricted to the interior of South Africa south of the Limpopo River. It contains Levallois cores and flakes, large blades, as well as elongated unifacial and bifacial points, often in hornfels. The triangular or leaf-shaped bifacial points with rounded bases are especially striking. At Border Cave the Pietersburg is found in layers with ages of between 227 and 82 kya (Wadley 2015). This technocomplex is also present at other stratified sites, for example, Cave of Hearths, Wonderwerk Cave, and Bushman Rock Shelter. As the Pietersburg covers such a large time span, it is possible that it contains several phases, as suggested by scholars such as Mason and Sampson (Wadley 2015).

During glacial MIS 6 MSA sites occurred on the coast and in the interior. At Elands Bay cave

situated on the West Coast, quartzite slabs were selected to produce flakes using the Planar-Orthogonal-Linear (POL) reduction system, the marker technology of this assemblage. These cores were not prepared as such, but the natural geometry of slabs was exploited to produce trapezoidal short as well as elongated blanks (Schmid et al. 2016). The earliest layers from Peers cave, also from the West Coast, document a similar technology, but here it occurs together with points and blades from Levallois cores. This type of technology has not been recorded at the ~162 kya cave 13B assemblage from Pinnacle Point on the southern Cape coast. This assemblage contains Levallois components and bladelets in association with shellfish, hinting at the earliest evidence for coastal occupation in South Africa (Marean et al. 2014). At Florisbad, an eponymous hornfels industry from Unit M, dating to ~157 kya, is "highly retouched" and has sidescrapers, blades, and flakes produced from multiple-platform cores and Levallois and discoidal technology (Wurz 2013). This "Florisbad industry" is broadly contemporaneous with the Pinnacle Point and West Coast assemblages, but there seems to be few technological or typological similarities between them. On current evidence inland South Africa was more highly populated than the coastal areas, but populations were fragmented and did not share technological strategies on a subcontinental scale.

In South Africa and Lesotho, there is a noticeable increase in the number of Middle Stone Age sites from MIS 5 onward (Wurz 2013), but spatial and chronological patterning remains obscure. The earliest interglacial assemblages from the coast may be those from the West Coast sites of Ysterfontein 1, Hoedjiespunt 1, and Sea Harvest in which short flakes in raw materials such as silcrete, calcrete, and quartz occur in association with rarer relatively thick blades that are frequently denticulated. The point component is almost nonexistent (Wurz 2013). The deposits from Klasies River contain one of the largest assemblages of MIS 5e-a artefacts in Southern Africa, made almost exclusively in quartzite. The early MIS 5e assemblage, the MSA l, Klasies River, or MSA 2a technocomplex, is characterized by blade technology (Wurz 2013) with characteristic denticulates. The MSA II, Mossel Bay, or MSA 2b technocomplex, dating to ~100–80 kya, is technologically related to the earliest technocomplex, but its distinguishing feature is the dominance of the unipolar recurrent Levallois reduction process for the production of relatively thick unretouched points. Other broadly contemporaneous assemblages from the Cape, from for example, Cape St Blaize, Pinnacle Point, Diepkloof, Nelson Bay Cave, and Blombos Cave, share some of the Klasies River Mossel Bay industry's technological characteristics, especially in relation to point production (Douze et al. 2015). Unretouched points are also well represented in the later Pietersburg from the north and Orangian assemblages from the Karoo region (Wurz 2013). A further example of a point-rich assemblage is a 125 kya hornfels industry from an open-air site at Florisbad in which 35 sets of artefacts could be refitted. The artefacts occur in primary context in association with fauna and hearths in distinct spatial patterns (Henderson and Brink 2001).

The Stillbay and Howiesons Poort technocomplexes are associated with glacial MIS 4. These are the most intensively analyzed phenomena in South Africa, and subsequently there is more knowledge on the reduction sequences, lithic techniques used, and associated non-lithic materials than for the other periods of the MSA (Wurz 2013). Double-pointed bifacial foliate points, occurring in a wide range of raw materials and sizes, are the marker type for the Stillbay technocomplex. Hard and soft hammer techniques, as well as occasional pressure flaking and heat treatment, were used to produce these points. Stillbay assemblages occur at Cape sites such as Blombos Cave, Peers Cave, Hollow Rock Shelter, Diepkloof, Varsche Rivier 003, and in KwaZulu-Natal at Sibudu and Umhlatuzana. Most sites are dated to around 71 kya, but earlier ages of around 80 kya at Hollow Rock Shelter and > 100 kya from Diepkloof have been reported (Wadley 2015).

The Howiesons Poort technocomplex has, since its inception, attracted much attention for its "Upper Paleolithic"-like backed geometrics

("East and Southern Africa: Howiesons Poort industry", "▶ Europe: Early Upper Paleolithic" (1)). It is the most widespread Middle Stone Age industry recorded in Southern Africa and is known from more than 32 sites south of the Zambezi River. Howiesons Poort sites in South Africa include the Howiesons Poort name site, Boomplaas Cave, Border Cave, Diepkloof Rock Shelter, Klasies Rivier cave 1A and 2, Klipdrift Shelter, Pinnacle Point, Klein Kliphuis, Varsche Rivier 003, Rose Cottage Cave, Sibudu, and Umhlatuzana. It also occurs at Melikane and Ntloana Tsoana in Lesotho and at Apollo 11 in Namibia. The dates for most Howiesons Poort assemblages range between 58 and 65 kya, but later dates 48 kya at, for example, Klasies River and earlier dates of up to 100 kya at Diepkloof occur (Wadley 2015). In the Howiesons Poort Levallois, blade and bladelet and flake reduction strategies were used (Delagnes et al. 2016). Often, but not always, fine-grained raw materials like silcrete or opaline were selected for the bladelets, blades, and backed artefacts. Smaller blade blanks, and sometimes flake blanks, were retouched by marginal backing into geometric shapes such as segments and trapezes. At Klipdrift Shelter methodical heating of silcrete formed an integral part of the reduction sequence (Delagnes et al. 2016). The Howiesons Poort backed artefacts are larger than those from the Later Stone Age Wilton industry and are on average around 40 mm in length. Another characteristic typological component of the Howiesons Poort, especially for the earlier phases, is denticulated and notched blades. The Stillbay and Howiesons Poort are associated with an increase in non-lithic innovations as discussed below. These shared innovations and lithic conventions over different regions of South Africa most likely indicate increased communication and connections of coalescent populations (Mackay et al. 2014) that occupied sites more intensively for longer periods (Wilkins et al. 2017). At Pinnacle Point MIS 4, communities responded to changing climatic conditions with increased utilization of quartz and outcrop quartzite and silcrete raw materials, on site reduction of raw materials, and a focus on flaking efficiency. Place provisioning (Mackay et al. 2014) where raw material such as silcrete was transported and stocked at base camps was probably a feature of the technological system.

In the post-Howiesons Poort period in Southern Africa, a contraction of populations and less interaction between groups occurred again. There is a dearth of sites in the southern Cape from this time period but a continued presence in the interior and high altitude sites. Unifacially retouched points frequently occur in post-Howiesons Poort assemblages. This is the case at Border Cave, Klein Kliphuis, Sibudu Cave, Diepkloof, Klasies Rivier, Umhlatuzana, Rose Cottage Cave in South Africa, and Melikane, Ntloana Tsoana, and Sehonghong in Lesotho. Post-Howiesons Poort sites have been described using various labels, including "MSA lll," "MSA 3," "post Howiesons Poort," "Sibudu," "Sibudan," and "informal late Middle Stone Age." The end of the MSA, represented by the period between 45 and 20 kya, contains "final Middle Stone Age" (Lombard et al. 2012) assemblages, and subcontinental or even regional patterns seem nonexistent. Characteristic Middle Stone Age elements such as points and blades persist until ~25 kya at sites like Boomplaas and Strathalan Cave (Deacon and Deacon 1999) and Apollo 11 in Namibia (Vogelsang et al. 2010). Other final Middle Stone Age assemblages are associated with a wide variety of types including hollow-based points and bifacial and unifacial points that occur at Rose Cottage Cave, Sibudu Cave, Heuningneskrans, Klein Kliphuis, Umhlatuzana, Melikane, and Sehonghong. The transition between the MSA and the LSA took place over a period of more than 20 kya (Bousman and Brink in press). At Border Cave, a ~43 kya old assemblage with small or microlithic flakes produced with bipolar knapping represents the first Early LSA (ELSA) assemblage in South Africa. Such assemblages occur in increasingly younger contexts toward the west, with the youngest dates recorded in Namibia around 23 kya. There is a lack of homogeneity in these assemblages, but bipolar technology and *pieces esquillee*s occur at sites such as Umhlatuzana, Kathu Pan, Rose Cottage, Putslaatge 8, Apollo 11, and Elands Bay Cave (Bousman and Brink in press).

The Middle Stone Age of Zimbabwe, Botswana, and Namibia is described using nomenclatures different from that used in South Africa and Lesotho, and this complicates drawing regional comparisons. Yet, it is a research priority to focus on the integration of human behavioral traces on a subcontinental level as the genetic evidence indicates a southern coalescence of early modern humans. Namibia's longest sequence site is Apollo 11 Cave (Vogelsang et al. 2010), and it contains elements such as bifacial points and backed artefacts in MIS 4 and 3, similar to contemporaneous technocomplexes from South Africa. There are not many stratified sites in the Kalahari region, but open-air sites abound. In Botswana, for example, there are more than 50 documented open-air MSA occurrences, especially in the areas around the Thamalakane and Boteti Rivers and the Makgadikgadi basin (Burrough 2016). Multisequence sites in Botswana in the Tsodilo Hills include the White Paintings Shelter, with 7 meters of deposits dating to the last 90,000 years, and Rhino Cave. Stratified sites in Zimbabwe include the Nswatugi Cave, Tshangula Cave, and Pomongwe Cave (Katsamudanga and Nhamo 2016). In Zimbabwe, Zambia, Namibia, and Botswana, many MSA assemblages are referred to as the Bambata industry. This industry may have occurred since the EMSA (Chiwara et al. 2017). At the open-air site #Gi in Botswana, for example, the 77 kya Bambata industry yields various types of retouched points, including short, broad foliate, triangular unifacial, and bifacial points (McBrearty and Brooks 2000). The Bambata technocomplex has also been identified in the Hwange National Park and at stratified sites such as Redcliff and Zombepata caves in Zimbabwe (Chiwara et al. 2017). In Botswana a late expression of the MSA occurs with the 45–55 kya Large Blade Industry at White Paintings Shelter, with artefacts similar to those found in the South African Howiesons Poort technocomplex (Robbins et al. 2016). The transition to the LSA in northern Southern Africa is associated with the Tshangula industry dating to around 35 kya (Katsamudanga and Nhamo 2016).

The Middle Stone Age Sequence Of East Africa

The MSA from East Africa is known mostly from low-density open-air sites, with lithic characteristics and variability from many areas still unknown (Tryon and Faith 2013). Due to geological exposure, MSA sites are concentrated within the East African Rift Valley system. In East Africa the transitional Sangoan industry is, as in other regions, also characterized by heavy-duty tools, such as choppers, pick axes, core scrapers, and core axes, in addition to small flake tools and Levallois cores. The Olkesiteti Formation at Olorgesailie, dating to around 220 kya, contains Sangoan-like picks, core axes, elongate bifacials, and Levallois cores interstratified with conventional Middle Stone Age artefacts. In Tanzania Sangoan artefacts are found at Isimila and Lake Eyasi (McBrearty and Brooks 2000), whereas the Lupemban's regional distribution extends from Central Africa to the Lake Victoria region of Kenya at, for example, Muguruk (Tryon and Faith 2013). The Gademotta and Kulkuletti site complex and the Kapthurin formation provide stratigraphic information for the earlier parts of the MSA. The Kapthurin formation is a Pleistocene sedimentary sequence in the Tugen Hills of the Kenya Rift Valley, west of Lake Baringo. It is visible over an area of ~150 km^2 and is about 125 m thick. This formation is divided into five members, from K1 at the bottom to K5 at the top, with the chronological framework determined by $^{40}Ar/^{39}Ar$ dating of tuffs. In the Kapthurin formation, assemblages with small Levallois cores are interstratified with those containing cleavers. MSA elements, including blades from cylindrical cores, Levallois flakes, and Acheulean tools, occur together. The earliest blade assemblages, dating to between 545 and 509 kya, come from the base of the K3 deposits. Blades have also been recovered from three younger sites in the Kapthurin formation that date to between 509 and 285 kya. This suggests that the development of blade technology in this region had its origins in the Acheulean and that blades formed a persistent, if small, part of the technological repertoire in the Middle Pleistocene.

"Early" MSA (EMSA) sites occur prior to the Last Interglacial and "Later" MSA (LMSA) sites

within or after MIS 5e. As in South Africa, EMSA sites are not many, but Levallois reduction methods are important in them. At the ~200 kya Koimilot site in the Kapthurin formation, for example, the preferential centripetal recurrent method for flakes and unidirectional and convergent strategies for Levallois points has been recorded. There is a change through time in the technological strategies followed to produce convergent tools in the EMSA at some sites. This is demonstrated in the central Rift Valley of Ethiopia at three obsidian rich sites at Gademotta and Kulkuletti with ages ranging from 280 to 100 kya. In the oldest sites, ETH-72-8B and ETH-72-1, there is continuity with the Acheulean, and convergent tools have been produced through a shaping process that involved the tranchet blow process for edge sharpening (Douze and Delagnes 2016). At the younger ETH-72-6 site, however, predetermined Levallois procedures, including the Nubian type 1 method, have been used for making convergent tools. The early *Homo sapiens* fossil sites in the Omo and Middle Awash valleys are associated with mixed Middle Stone Age and Acheulean assemblages. Foliate bifaces, hand axes, picks, and lanceolates are common in surface finds but rare in stratified contexts in these sites. The MSA tools are in high-quality raw material such as cryptocrystalline silicate and chert, and core reduction was through the radial or centripetal Levallois and discoidal methods. A somewhat different pattern occurs in the Kapedo Tuff sites in Kenya, dating to ~135–123 kya, as well as the Turkana and the Baringo basins. Here different raw materials, for example, elongated lava cobbles, facilitated the inclusion of more elongated and larger products in assemblages (Tryon et al. 2008).

LMSA sites in East Africa typically contain Levallois flakes, blades, and a variety of types of points, including small carefully worked points, for example, at GvJm16 at Lukenya Hill, Songhor, Prolonged Drift, and Cartwright's Site in Kenya and the Nasera Rockshelter in Tanzania (Tryon and Faith 2013). It remains a challenge to document lithic technological geographical and temporal variation in East Africa, but statistical analysis of the variation within major artefact classes (Tryon and Faith 2013) indicates a unity in assemblages <75 kya. These assemblages are characterized by increased frequencies of backed pieces, bipolar technology, blades, grindstones, anvils, as well as beads and ochre. This is the case at sites like Nasera Rockshelter, Mumba, Porc Epic Cave, Mochena Borago, and the undated assemblages from Mtongwe (Tryon and Faith 2013). Very small bifacial points, of between 2 and 4 cm in length, occur from the Rusinga and Mfangano islands to the East African Rift System. This large distribution likely represents a shared technology of groups that inhabited tropical grasslands (Faith et al. 2016). The transition to the LSA is varied across the East African region and occurred over a period of 30–60 kya (Tryon and Faith 2016). Elements such as backed pieces, bipolar technology, ochre, grindstones, and anvils are continuous between the LMSA and LSA, but there is a marked proliferation of ostrich eggshell beads, and the long-distance movement of obsidian intensifies (Faith et al. 2016). In Tanzania at the Mumba Rockshelter, the transition occurs either at 55 kya or 40–35 kya (depending on the interpretation of the dating and stratigraphy) and at Kisese II rockshelter from 40 to 35 kya. In Kenya, at Enkyapune ya Muto, the transition relates to 40–50 kya assemblages, while at GvJm-22 at Lukenya Hill, the transition is between 26 and 50 kya. The Middle Stone Age persists until later in other regions, for example, until 36 kya in the Lake Victoria basin of western Kenya and until 29 kya in Mozambique (Blegen et al. 2017).

Behavioral Milestones and the MSA

One of the major issues discussed for the Middle Stone Age, especially for South Africa, is whether early humans acted in ways that could be considered "modern" or typically human. Terms such as "symbolic" and "complex" are used to evaluate cognition and behaviors associated with these groups. There is, however, debate on whether such terms are appropriate and whether archaeological evidence can even shed light on this topic (Shea 2011). The behavioral and cognitive strategies of present-day and ethnographically known people are hyper flexible and intimately linked to

specific environmental and social contexts. Moreover, the archaeological record very rarely preserves perishable items and structures that might have been used in the past in such behaviors and strategies. Until recently, the criteria used to recognize "modern behavior" were decidedly Eurocentric, sourced from the archaeological signals associated with the Upper Paleolithic (Deacon and Deacon 1999). According to some authorities (e.g., Klein 2009), art; ornamentation; the widespread shaping of bone, ivory, and shell; and spatial organization of camp floors appeared relatively sudden as a "package" in the Upper Paleolithic of Europe. From this perspective it is only when this package of behaviors can be detected in the MSA of Africa, from around 50,000 years ago, that behavioral "modernity" can be inferred. Klein (2009) suggests that a genetic mutation occurred at ~50 kya in African populations that enabled language and symbol use. Some of these types of behaviors already occur in the early MSA of Africa, but they disappear again. This fluctuation may be related to population dynamics and the rate at which innovations are spread and maintained rather than cognitive capabilities per se. The ongoing transmission and maintenance of innovations rely on highly connected populations (Mackay et al. 2014).

A distinct possibility is that many of the traits associated with "modernity" were present at least from the mid-Pleistocene after 600 kya. Prepared core technology, for example, entails hierarchical behavior and cognitive demands similar to those involved in complex language (Muller et al. 2017). The transport and transformation of lithic raw material through heat or fire also indicate complexity of thought and behavior. Provenancing studies of lithic raw materials that use geochemical fingerprinting of silcrete and obsidian in Southern Africa and East Africa, respectively (Nash et al. 2016; Tryon and Faith 2013), indicate that MSA populations were highly mobile and transported raw materials in excess of 300 km. Silcrete and other raw materials were heat treated to improve its flaking capability (Schmidt et al. 2017; Wadley et al. 2017). Hafting represents a major innovation and an early milestone in the development of complex cognition (Wadley 2015). Bone or stone artefacts are hafted when they are set in handles of organic material to produce multicomponent tools. During this process different types of materials are combined, and the series of decisions and activities imply complexity or even an "industrial revolution" (Barham 2013). In the MSA various forms of unretouched pieces, Levallois points, and backed artefacts were hafted and propelled by hand. Hafting of Levallois points occurred at ~279 kya in East Africa (Sahle et al. 2013) and somewhat earlier in Southern Africa at Kathu Pan 1(Wilkins et al. 2012). The origins of bow and arrow technology, long associated with the Upper Paleolithic of Europe, are linked to the Howiesons Poort. Metric analyses, use wear, and microtrace studies have shown that microlithic quartz backed artefacts from Umhlatuzana and Sibudu Cave were hafted and used as arrow inserts (Wadley 2015; Figs. 2 and 3) (▶ Stone Tool Usewear and Residue Analysis). MIS 4 bone points, from Peers Cave, Sibudu, and Klasies River, were also used to tip arrows (Bone Technology). Experimental research is one of the most promising avenues to explore ancient cognition (▶ Cognitive Archaeology) and plays an important role in investigating the early use of projectile systems in the MSA. Experiments were, for example, done to investigate how mastic was produced to facilitate hafting of Howiesons Poort backed artefacts. Microresidues on the Sibudu Cave backed artefacts provided the clues for identifying the components of the prehistoric adhesives. Several ingredients including ochre, gum, and a fatty substance had to be mixed and heated to a specific temperature to ensure the correct degree of elasticity for successful hafting. Keeping this complex chain of decision-making steps in mind is typical of the thought processes guiding modern day technological procedures (Wadley 2015).

These hafting procedures and hunting technologies imply a sophisticated level of cognitive and behavioral adaptability, similar to that of current hunter-gatherer groups (▶ Hunter-Gatherers, Archaeology of). MSA hunters, like their modern counterparts, displayed flexibility when choosing a particular hunting technique and weaponry. They selected, for example, snares, bows and

Southern and East African Middle Stone Age: Geography and Culture, Fig. 2 Quartz segments and backed pieces from Sibudu Cave, KwaZulu-Natal, South Africa (Lombard and Phillipson 2010)

arrows, or spears depending on the prey desired (Wadley 2015). The choice of prey on the other hand has led to the interpretation that MSA people from the Cape coast were technologically less advanced and efficient, and therefore less competent hunters, than those from the LSA (Klein 2009). In the LSA more dangerous game, such as wild pigs and buffalo, and in the MSA more docile species, like the eland, were hunted. LSA people also exploited marine mollusks, tortoises, airborne birds, young seals, and fish more extensively and intensively than MSA people. These contrasting behaviors are based on assemblages dated to before 60 kya and after 20 kya. The period between these dates has not been documented as there is a general lack of sites in the southern Cape during this period. The differences in species abundance in the MSA and LSA do not necessarily reflect cognitive capabilities but simply resource intensification imposed by higher population densities in the LSA (Deacon and Deacon 1999). Faith and others also point out that environmental changes associated with the onset of the last interglacial, starting after 18 kya, led to the shrinking of grassland habitat that supported grazing taxa and hence the

Southern and East African Middle Stone Age: Geography and Culture, Fig. 3 Left: reconstructed arrow, tipped with a transversely hafted segment. Right: segments and backed pieces from Sibudu Cave and Umhlatuzana Rockshelter with impact fractures consistent to those observed on similar artefacts that were used as transverse tips in experimental arrows (Lombard and Phillipson 2010)

availability of these large ungulates to hunt. This necessitated an expansion of diet breadth to include more intensive exploitation of shellfish, flying seabirds, tortoises, and fish in the LSA. In East Africa, vegetation changes driven by Quaternary climate cycles also influenced grassland expansion and contraction. During periods that grasslands were more extensive, certain ungulates, and perhaps also human groups, dispersed more widely. The increased presence of diagnostic technological markers such as very small bifacial points at Late Pleistocene or MSA/LSA sites such as Rusinga and Mfangano Islands, GvJm-16 at Lukenya Hill in Kenya, Nasera Rockshelter in Tanzania, and Aduma in Ethiopia may indicate such connections between populations (Faith et al. 2016).

Like hafting, the utilization of pigments also harks back to the Middle Pleistocene. Even the earliest identified pigments were modified and bear striations on their surfaces. In the Fauresmith from Kathu Pan 1, Wonderwerk Cave and Canteen Kopje pigments, especially specularite and also hematite, have been used, a practice that became more widespread by 300 kya in the Northern Cape region (Watts et al. 2016). The earliest ochre use in East Africa has been documented in the Kapthurin formation, Kenya, at GnJh-15, dating to ~284–500 kya (Tryon and Faith 2013). At Pinnacle Point striated ochre occurs at 162 kya introducing a period of more frequent ochre use at South African sites (Marean et al. 2014). In the MSA pigments were intensively worked, and this resulted in fragments and crayons with smoothed edges, such as the ~90 kya subtriangular ochre crayon from Klasies River (Fig. 4). There are grindstones from South and East African Middle Stone Age sites that retain traces of pigment indicating that it was sometimes powdered before use. Pigments like ochre could also have been

Southern and East African Middle Stone Age: Geography and Culture, Fig. 4 Ochre crayon, Mossel Bay technocomplex, Klasies River

Southern and East African Middle Stone Age: Geography and Culture, Fig. 5 (**a** and **b**) In situ ochre-processing toolkits from Blombos Cave

processed and used in a liquid form. Two ~100 kya ochre-processing toolkits have been recovered from Blombos Cave (▶ Blombos Cave: The Middle Stone Age Levels). The coeval and spatially related toolkits consist of *Haliotis midae* (abalone) shells and are associated with grinders, stone artefacts, bone, and ochre (Fig. 5a, b). Inside the abalone shell of toolkit A (Fig. 5a), a 5-mm-thick red compound adheres to the inner surface. The compound consists of ochre, fragments of spongy bone, probably the origin of fat that may have acted as a binder, charcoal fragments, and quartz and quartzite microflakes. A quartzite cobble that was used as percussor and grinder were also found inside the toolkit. The other abalone toolkit (Fig. 5b) also contains a thick red compound sticking to the inside of the shell. It is not known what the ochre liquid was used for, but it may have been applied as paint on a surface. This find shows that the conceptual capability to source, combine, and store substances was present *in some populations* 100 kya.

Pigments played a crucial role in MSA societies. Large quantities of hematite have been, for example, extracted at the Lion Cavern site in Swaziland, probably dating to ~40 kya (Wadley 2015). Another indication of its importance,

S

Southern and East African Middle Stone Age: Geography and Culture, Fig. 6 Engraved ochre, Stillbay techno-complex, Blombos Cave

perhaps in the social lives of MSA people, comes from Porc Epic, Dire Dawa, Ethiopia. Here 21 ochre-processing tools, including upper and lower grindstones, were found in association with numerous fragments of ochre, concentrated in an area specifically focused on ochre processing. The technical steps used in reducing and processing the ochre illustrate considerable behavioral complexity and sophistication (Rosso et al. 2017). The earliest representational art in Africa, dating to around 30 kya, is the well-known painted slabs from Apollo 11 cave. These drawings, executed with pigment crayon, are on seven loose slabs ("art mobilier"), and they depict a therianthrope, geometric patterns and animals (Vogelsang et al. 2010).

Several pieces of ochre with engravings, dating to between ~72 and 100 kya, have been recovered from sites in South Africa. The signature piece is a small ~77 kya slab of dark red ochre from Blombos Cave. It shows a stone tool engraved cross-hatched pattern bounded by parallel lines (Fig. 6). A comparable engraving on a smaller ochre fragment was found at Klein Kliphuis in a layer that dates to between ~80 and 50 kya (Wadley 2015). In the MSA of South Africa, the convention of engraving extends to other raw materials such as bone and ostrich eggshell. At Klasies River four parallel lines have been engraved with a lithic point on a midshaft fragment of a limb bone associated with the early Howiesons Poort (Fig. 7). More spectacular are

Southern and East African Middle Stone Age: Geography and Culture, Fig. 7 Engraved bone, Howieson's Poort technocomplex, Klasies River

the engravings on ostrich eggshell from Diepkloof and Klipdrift shelter in the Cape uncovered in investigations led by Texier and Henshilwood. It is interesting that a finite number of abstract geometric motifs have been identified. At Diepkloof a cross-hatched band and sub-parallel and converging lines dominate. At Klipdrift the same set of patterns, in addition to a diamond-shaped motif, occurs. There is a strong possibility that the engravings were made on eggshell containers (Wadley 2015). In the Howiesons Poort levels from Apollo 11 in Namibia, potential eggshell flask apertures (represented by 23 pieces) have been found, together with 2 small fragments of ostrich eggshell (OES) with intentionally engraved patterns (Vogelsang et al. 2010). The oldest engraved OES found in Eastern Africa is from Goda Buticha, Ethiopia, dating to between ~43 and ~34 kya. Some of the motifs are similar to those from the South African sites, and the engraved lines also align along similar axes (Assefa et al. 2018).

Beads are artefacts that serve as personal ornaments in current and recently known societies and might have had a similar symbolic function in the MSA. The earliest beads, made from marine shell, occur around 100 kya in North Africa and the Near East. There are also early beads, dating to MIS 4, from the South African MSA, and these have been described in papers by Vanhaeren, Van Niekerk, Henshilwood, d'Errico, and Wadley, among others (Wadley 2015). More than 68 *Nassarius kraussianus* shell beads have been found from Stillbay layers dating to ~72 kya at Blombos Cave (Fig. 8). Microscopic study revealed that these tick shells were pierced with a bone tool to create a perforation. Discrete use-wear facets on the beads indicate that the shells were strung, possibly on cord or sinew, and worn as personal ornaments. The beads have been arranged in different patterns through time. Very small residues of ochre inside some beads may have been caused by deliberate coloring or transference of ochre when worn. Three *Afrolittorina africana* shells from Sibudu, also in the Stillbay levels, were also deliberately pierced and might have been worn as beads. The first ostrich eggshell beads appear earlier than 40 kya in deposits in Southern and East Africa. The earliest indication of the use of OES may be from Apollo 11. Three OES pieces with smoothed edges, similar to LSA OES pendants, have been described from the Howiesons Poort technocomplex (Vogelsang et al. 2010). Other early examples dating to ~50 kya are from level V at Mumba Rockshelter and Magubike Rockshelter in Tanzania (Wadley 2015). Around ~ 40 kya there is an increase in the number of OES beads at Enkyapune ya Muto in Kenya, Nswatugi in Zimbabwe, and Boomplaas, Bushman Rock Shelter, Cave of Hearths, and Border Cave in South Africa (McBrearty and Brooks 2000). OES beads become very commonplace in the Later Stone Age of Southern and East Africa.

Formal bone tools were also produced in the Middle Stone Age. These are tools or bone implements that have been modified with techniques such as grinding, scraping, or cutting (▶ Bone Tools, Paleolithic). The barbed and unbarbed bone points from the Katanda sites in the Semliki Valley dating to ~90 kya ago are the

Southern and East African Middle Stone Age: Geography and Culture, Fig. 8 *Nassarius kraussianus* beads, Stillbay technocomplex, Blombos Cave

oldest formal bone tools discovered in Africa yet (McBrearty and Brooks 2000), whereas the largest collection of bone tools is from Blombos Cave, from the Stillbay technocomplex. Bone tools also occur at Sibudu Cave where d'Errico and colleagues identified specialized types such as wedges, *pièces esquillées*, pressure flakers, smoothers, sequentially notched pieces, awls, and a projectile point (Wadley 2015). Notched bone, most probably with a nonfunctional purpose, occurs in the Mossel Bay levels at Klasies River (Fig. 9), at Apollo 11 in the Stillbay levels (Vogelsang et al. 2010), and at Sibudu Cave in the Howiesons Poort levels (Wadley 2015). There are also MSA bone tools from White Paintings Shelter dating to ~38–50 kya. The bone implements such as awls and points and a wooden digging stick from a ~44 kya Border Cave assemblage show remarkable similarities to current San material culture (d'Errico et al. 2012).

Investigations into the organization and use of space also provide insights into the minds and behavior of MSA people. In Wonderwerk Cave the Fauresmith layers built up in a dark space at the very back of this deep cave. This area may

Southern and East African Middle Stone Age: Geography and Culture, Fig. 9 Notched bone, Mossel Bay technocomplex, Klasies River

have been specifically selected for occupation due to the sensory experience that it may have facilitated. Watts et al. (2016: 299) speculate that activities such as "fire-lit, body-painted, song- and dance performances, the performers glittering and red" may have taken place here. At MSA sites where preservation is less than ideal, it is generally problematical to detect whether space was structured according to the same social and cognitive rules as those used by modern people. Micromorphological and geomorphological have been used to show that, at Sibudu Cave in the ~ 58 kya layers, combustion features such as hearths and bedding heaps were maintained. Phytoliths from ~77 kya layers at this cave further indicate cultural use of space through the use of sedges and aromatic leaves to construct bedding (Wadley 2015). The clearest organization of space in the MSA occurs at a site investigated by Opperman, Strathalan Cave B, dating to ~22 kya. Here bedding heaps were concentrated against one sheltered wall of the cave, and four hearths were built in the central area. Bone fragments and lithics were discarded in this area (Deacon and Deacon 1999). Plant materials such as *Watsonia*, sagewood, and aloe were also preserved. Other Southern African MSA sites also yielded plant material such as seeds, corms, and charcoal (Wadley 2015). Grindstones from the MSA hold much potential for understanding past plant processing (Shoemaker et al. 2017). Starch granules have, for example, been preserved on 105 kya grinding stones at Ngalue in Mozambique, as Mercader and colleagues have shown. Even though plant gathering and use must have been of the most pervasive and important activities in the MSA, it remains an understudied aspect of African archaeology (Wadley 2015).

Conclusion

In Southern and East Africa, the transition from the ESA to the MSA occurred from ~500 to 285 kya ago, but the absence of good chronometric control and scarcity of multi-sequence sites prevent a precise grasp of this process. During the transition Middle Stone Age and Acheulean elements frequently appear together in sites. The transition to the LSA was similarly a protracted process that took place between

60 and 20 kya in East Africa and between 40 and 20 kya in Southern Africa. The earliest date for Middle Stone Age occurrences without LCTs in Southern and East Africa is around ~285 kya. Due to the presence of more deeply stratified cave sites in Southern African MSA, more progress has been made toward creating an overarching regional culture-historical framework for this region. The MSA is typified by prepared core or Levallois technology and in addition discoidal, blade and platform reduction processes were used. Flakes, blades, and points were frequently hafted and used in projectile weapons. MSA assemblages do not contain many retouched artefacts, but scrapers, notched, denticulated and backed artefacts, and bifacial and unifacial points occur. Backed geometrics and retouched points are used to document regional and temporal patterns in Southern and East Africa. In the Stillbay and Howiesons Poort technocomplexes, for example, these marker types, together with other complex artefacts, occur on a subcontinental level. This is thought to reflect the cultural signal of coalescent populations in MIS 4 in South Africa. Similarly, the very small bifacial points that occur over an extensive geographical area within East Africa in the Late Pleistocene may indicate a regional system of connection between groups. MSA stone, bone, and pigment technologies reveal remarkable extended production sequences and complexity. Lithic raw materials were obtained from far away sources and heat treated to achieve desired results. Much effort was invested in artisan activities such as engraving of geometric designs on pigment and shell, producing shell beads, formal bone tools, and processing ochre. In addition hunting technologies were highly flexible, and specific hafting configurations and types of insets in composite weapons were consciously selected. There are also indications that plants were used as food and medicine and that MSA groups organized and maintained their living spaces. The research discussed here reveals that modern humans' evolutionary roots reach into the Middle Pleistocene and that these hunter-gatherers were able to execute complex behavioral actions.

Southern Ocean and Antarctic Maritime Archaeology

Matthew Carter[1] and Emily Jateff[2]
[1]La Trobe University, Melbourne, Australia
[2]Australian National Maritime Museum, Pyrmont, NSW, Australia

Introduction

Professional archaeology has been practiced in the Southern Ocean and Antarctic region since the 1970s with archaeologists from Australia, Argentina, Brazil, Chile, New Zealand, the United Kingdom, and the United States undertaking the survey, recording, and excavating a number of maritime sites. This work has been undertaken primarily to create inventories of historic places and to aid in the conservation of historic buildings, and as a result, this work has been almost exclusively terrestrially based.

Definition

The Southern Ocean and Antarctic cover more than one-eleventh of the Earth's surface. Antarctica is the fifth largest continent in the world, while

the Southern Ocean is the fourth largest ocean, extending from the shores of Antarctica to 60° south to the approximate extent of the Antarctic Convergence (although this definition is often broadened to include the Subantarctic Islands south of 45° latitude).

The Southern Ocean comprises the world's southernmost body of water and includes parts of the Drake Passage, the Scotia Sea, the Weddell Sea, the King Haakon VII Sea, the Cosmonaut Sea, the Cooperation Sea, the Davis Sea, the Mawson Sea, the D'Urville Sea, the Ross Sea, the Amundsen Sea, and the Bellingshausen Sea. Throughout its waters are islands within the Antarctic continental shelf such as the South Orkney Islands, South Shetland Islands, Balleny Islands, and Scott Islands and outside this area the Subantarctic Islands of the Falkland Islands, South Georgia and the South Sandwich Islands, Bouvet Island, the Prince Edward Islands, the Crozet Islands, the Kerguelen Archipelago, Heard Island, the McDonald Islands, Macquarie Island, the Auckland Islands, Bounty Island, Campbell Island, the Antipodes, and the Snares.

The amount of ice within the Southern Ocean is enormously variable and fluctuates seasonally; in winter the ocean freezes outward from Antarctica to approximately 65° south latitude in the Pacific sector and 55° south latitude in the Atlantic sector a greater than a sixfold increase in area. At some coastal points, intense persistent drainage winds from the interior keep the Antarctic shoreline ice-free throughout the winter.

The Southern Ocean is 4000–5000 m deep over most of its extent with only limited areas of shallow water with even the Antarctic continental shelf being generally narrow and deep, its edge lying at depths of 400–800 m. The ocean's greatest depth is 7235 m at the southern end of the South Sandwich Trench.

The Southern Ocean and Antarctic is characterized by frequent intense cyclonic storms caused by the temperature contrast between ice and open ocean with the area from about latitude 40 south to the Antarctic Circle recording the strongest average winds anywhere on Earth.

World Heritage Sites and Legislation

The islands in the Southern Ocean and their surrounding waters are protected by an interwoven web of legislation aimed at protecting both natural and cultural resources. Each island comes under the legislation of its sovereign nation which provides the framework for the management and protection of heritage sites. In addition, many of the islands including Auckland Island, Campbell Island, Heard Island, and Macquarie Island have been designated as "nature reserves," and in the last two decades, the waters surrounding these islands have been also made into marine reserves further restricting activities that may be harmful to natural and cultural resources. Significantly, the Heard Island, the New Zealand Subantarctic Islands, the Macquarie Island, and the Tristan da Cunha Islands are all UNESCO world heritage sites based on their outstanding universal natural values.

The Antarctic Treaty System (ATS) is one of the most successful examples of international law ever created. Ratified in 1959 by 25 consultative parties including those previously involved in Antarctic action (highly active signatories include Australia, Argentina, Belgium, Chile, France, Japan, New Zealand, Norway, South Africa, Russia, the United Kingdom, and the United States), the Antarctic Treaty created rules and regulations for exploration and exploitation of the Southern Continent. Drafted in the spirit of peaceful scientific international agreement, all activities may be monitored or "observed" by any nation, and disputes must be settled by common vote. Consultative parties cannot resign or be expelled from membership, although nations are allowed to ratify and become a consultative party if conducting research in Antarctica.

Seven nations (Australia, New Zealand, the United Kingdom, Argentina, Chile, France, and Norway) claim sovereign rights to territory in Antarctica. Under the 1959 Antarctic Treaty and subsequent 1999 Protocol on Environmental Protection to the Antarctic Treaty, or Madrid Protocol, territorial claimant nations are responsible for protection of cultural heritage under pertinent national legislation. However, signatories remain

at odds over recognition of marine claims, an issue that has implications for Antarctica's submerged cultural heritage sites. Marine areas (e.g., the Australian Antarctic Territory [AAT] Exclusive Economic Zone [EEZ]) may not be recognized by states other than the claimant nation, a dubious measure of protection for heritage sites in disputed waters.

Documents within the ATS that relate to cultural heritage are the Antarctic Treaty Recommendation VII-9, which regulates scientific endeavor, and the Madrid Protocol. The Madrid Protocol entered into force on 14 January 1998, with the goal to, as per Article 3, avoid "degradation of, or substantial risk to, areas of biological, scientific, historic, aesthetic or wilderness significance." Annex V on Area Protection and Management outlines the procedures for site nomination as an Antarctic Specially Protected Area (ASPA) or Antarctic Specially Managed Area (ASMA) and provides for permitting procedures. In order to be recognized as a historic site or monument, sites must first be accepted as (or be located within) an ASPA or ASMA, which requires a process of nomination. All sites are then entered on the Antarctic Sites and Monuments List. Guidelines (Resolution 5) were submitted at the 2001 Antarctic Treaty Consultative Meeting (ATCH) that offer blanket protection for all pre-1958 historic sites and artifacts and recommend best archaeological practice for necessary disturbance of remains. Oversight is through the ATS and the Scientific Committee on Antarctic Research (SCAR) and can be accessed via the International Polar Heritage Committee website (www.polarheritage.com).

Maritime Sites on the Antarctic Sites and Monuments List

While many sites on the Antarctic mainland have associations with maritime activities (such as whaling and sealing sites and research stations), only three dedicated maritime archaeological sites are currently located on the Antarctic Sites and Monuments List. These sites are the whaling station at Whalers Bay, Deception Island (No.71), nineteenth-century wreckage located on the beach at Elephant Island by a naval expedition in the 1990s (No.74), and Cape Denison, Commonwealth Bay (No.77), which is the only listed site that incorporates an underwater object (a bow anchor associated with Mawson's vessel *Aurora*) that has not yet been located. Commonwealth Bay is managed as ASMA 3. Two sites (Whalers Bay and Elephant Island) fall within the UK territory. The third site (ASMA 3) is located within the AAT and managed by Australia.

Historical Background

Polynesian seafarers were the first humans to venture into the Southern Ocean region with archaeological evidence suggesting that they discovered and briefly occupied the Auckland Islands in the Subantarctic Island group some 650 years ago (Anderson in Dingwell et al. 2009: 35). European exploration in the Southern Ocean, and the eventual discovery of Antarctica, began with the voyages sponsored by the Portuguese Prince Henry the Navigator in the early fifteenth century. The Portuguese rounding of the Cape of Good Hope in 1487–1488 and the crossing of the Indian Ocean in 1497–1499 distanced both Africa and Southern Asia from the hypothesized *Terra australis incognita*, and later, the discovery of the Strait of Magellan 1519–1522 and Drake Passage 1577–1580 also separated South America from the fabled southern land confirming the possibility of world circumnavigation via the southern hemisphere. The surveying of the coast of Australia by the Dutch explorer Abel Tasman in 1644–1645 provided further information as to the extent of the Southern Continent, while almost a century later, French expeditions from 1738 onward began to discover isolated islands in the Southern Indian Ocean. Identification of the Southern Ocean however is credited to Captain James Cook who during three expeditions between 1771 and 1780 discovered South Georgia and the South Sandwich Islands and crossed the Antarctic Circle for the first time. The subsequent publication of accounts of Cook's voyages heralded the start of both sealing and whaling in the Southern Ocean

region. Descriptions of the abundance of seals on South Georgia led to a rush of sealing vessels into the Southern Ocean from the late 1780s. The search for unexploited stocks of seals led to the discovery of many other Southern Ocean island groups such as the Antipodes (1800), Auckland Islands (1805–1806), Bounty Islands (1807), and Campbell and Macquarie Islands (1809–1810). Each island was stripped of its stocks so that by 1850s there were few southern fur seals left; however, the use of the Great Circle sailing routes by naval and merchant ships travelling through the Southern Ocean from around this time continued the discovery of islands between the latitudes of 50° and 60° south.

Discovering Antarctica

Early Western exploration of the Antarctica continent was attempted for a number of reasons: some nations were interested in locating new fertile whaling grounds; others sought to locate the South Magnetic Pole, and others to acquire territory. The first recorded sighting of the Antarctica continent was by Russian explorer Thaddeus von Bellingshausen who circumnavigated the Antarctic south of Cook's route in 1819–1821, yet American whaler *Nathaniel Palmer* is the first to land men on the Antarctica continent in 1821. French explorer Jules Dumont D'Urville was instructed to reach and claim the South Magnetic Pole for France. He relied on coordinates predicted by mathematician Carl Gauss, but ended up west of the mark. With ships *Astrolabe* and *Zelee*, he sighted a section of the Antarctic coast and claimed Terre Adelie for France in 1840. Charles Wilkes' US Exploring Expedition also searched for the South Magnetic Pole in 1838–1842, encountering the French ship *Astrolabe* in Antarctic waters. Bipolar adventurer James Clark Ross led the British bid for the South Magnetic Pole from 1839 to 1843, with the ships *Erebus* and *Terror*. Ross noted his rivals' routes and headed the other direction, narrowly missing the pole. Ross explored more of Antarctica than any previous adventurers, naming features such as Mounts Erebus and Terror and the Ross Sea. A British scientific expedition in 1872–1876 on *Challenger* circumnavigated the continent, produced valuable deep sea soundings and helped initate the next phase of Antarctic exploration.

The First International Polar Year (1882–1883) saw an increase in expeditions, leading to what is known as the "Heroic Age" of polar exploration. Eight nations sent exploratory expeditions to the south lands for national honor, pride, and scientific endeavor. Not until the Space Race of the 1960s would such a feat be seen again. This period is usually said to end with the tragic voyage of Ernest Shackleton in 1914–1916 which resulted in the loss of *Endurance* to pack ice. Only a few survived by rowing to South Georgia (Elephant Island) in the tender *James Caird.*

In 1898, *Belgica* was the first vessel to overwinter in Antarctica, and in 1899, Carsten Borchgrevink's *Southern Cross* was the first to set up a temporary camp on the mainland. Erich von Drygalski's Gauss 1901–1903 Expedition became trapped in the pack ice. This expedition charted part of Antarctica, including Drygalski Island. Baron Otto Nordensköld and the 1901–1903 Swedish Antarctic Expedition resulted in the loss of vessel *Antarctic*, which was crushed in pack ice. Robert Falcon Scott's first expedition (in vessel *Discovery*) was from 1901 to 1904, setting a new farthest south record and charting territory. The Scottish National Antarctic Expedition (1902–1904) charted portions of Coats Land along the Weddell Sea, and in 1903, a French team led by Jean-Baptiste Charcot set sail in *Français* to rescue the Nordensköld party. While Nordensköld was eventually rescued by Argentinean vessel *Uruguay*, Charcot charted portions of Graham Land and Loubet Land.

The South Magnetic Pole was finally achieved in 1909 by the Northern Party of the British Antarctic Expedition on *Nimrod,* Ernest Shackleton in command. Charcot returned to Antarctica in 1908–1910 to continue exploration of the continent. In 1910, Nobu Shirase led the Japanese Antarctic Expedition in *Kainan Maru.* It all came to a head on 15 December 1911, when Roald Amundsen's South Pole Expedition beat Robert Falcon Scott, of the British *Terra Nova* Expedition to the South Pole. On the return

journey, Scott and his party succumbed to the elements. The 1911–1914 Australasian Antarctic Expedition (under Douglas Mawson in vessel *Aurora*) charted the coastline between Cape Adare and Mount Gauss. Shackleton's Imperial 1914–1917 Trans-Antarctic Expedition (*Endurance*) was 1915–1917. Supported by the Ross Sea Party with Aeneas Mackintosh in charge, they succeed in laying depots across the Great Ice Barrier. Shackleton's final voyage 1921–1922 on vessel *Quest* continuously mapping the Antarctic continent but resulting in Shackleton's death and burial at South Georgia Island. A final footnote is the first Antarctic flight, made by Hubert Wilkins in 1928. For further information, see Headland (2009).

By the 1870s the falling number of whales in northern waters saw German, Scottish, and Norwegian whalers exploring and taking whales from the waters of the Southern Ocean down as far as the Antarctic Peninsula. In 1904 this interest was cemented by the establishment of the first Antarctic land-based whaling station on Georgia Island. This success of this station soon saw the establishment of other whaling operations on South Georgia and the extending of their range southward to the southern Scotia Sea and Antarctic Peninsula. By 1912 Norwegian whaling factory ships were operating in the open waters or the Southern Ocean using the edge of the Antarctic ice field to provide the calm waters they needed to hunt and process their prey. The 1920s saw a massive increase in demand for whale oil which saw the rapid growth of the industry; however, overproduction caused the market to collapse, and in 1931 an International Convention for the Regulation of Whaling was established.

After the Second World War, scientific exploration of the Antarctic continent again increased. Fifty-five research stations were established as a result of the First International Geophysical Year (1957–1958). A third cycle of resource extraction (modern fishing and whaling), led by Soviet, Chilean, and Japanese vessels, began in the 1960s and continues today. Fishing below 60° south latitude is now regulated by the Convention on the Conservation of Antarctic Marine Living Resources (CCAMLR) (Fig. 1).

Archaeology

The relatively recent exploration and settlement of the islands in the Southern Ocean and of the Antarctic continent itself, the rugged conditions, and the loss of many vessels have combined to create a rich maritime archaeological record which has only recently become the subject of archaeological investigation.

The archaeological remains from various sealing expeditions in the Southern Ocean and Antarctic have been investigated by researchers from Australia, Chile, South Africa, and New Zealand. This work has included the survey of sealing sites on Campbell Island (Palmer and Judd 1981; Prickett et al. 2012), the Prince Edward Islands (Cooper and Avery 1986), and Kerguelen Island (Le Mouël 2004), while excavations have been undertaken on Auckland Island (Dingwell et al. 2009), Heard Island (Lazer and McGowan 1990), Macquarie Island (Townrow 1989), and the South Shetland Islands (Stehberg and Cabeza 1987). The transient nature of most sealing expeditions means that the archaeological remains from this industry are typically slight; however the investigation of sealing sites in this area has covered not only the camps that the sealers used but also production and storage sites providing insights into both the domestic and industrial aspects of this industry. The majority of archaeological work directed toward sealing on these islands has been undertaken by government agencies in order to create inventories of historic sites and to gain sufficient information to make appropriate management recommendations for these sites. These surveys and excavations have also raised a number of academic questions including the role of sealing in the expansion of capitalism in the nineteenth century, the organization of the sealing industry, the technology and the international commercial networks, and the archaeology of communities in isolation.

Shore-based whaling sites have been investigated at a number of sites within the region. The earliest whaling station investigated is the 1850 Southern Whale Fishery Company's whaling station at Port Ross in the Auckland Islands. In 2003 a New Zealand Department of Conservation

Southern Ocean and Antarctic Maritime Archaeology, Fig. 1 National claims to Antarctic Territory. Map produced by the Australian Antarctic Data Centre, 2004. Hobart: Australian Antarctic Division

S

expedition to the Auckland Islands surveyed the remains of this settlement which at its height comprised some 30 buildings and around 200 colonists (Dingwell et al. 2009). This archaeological survey reconstructed from the surface evidenced the general layout and many of the features of the settlement providing insights into the character and composition of this failed colonial enterprise. Whaling stations from the early twentieth century have also been investigated including the Te Awaiti whaling station (1909) and Cook's whaling station (1911) on Campbell Island (Palmer and Judd 1981; Prickett et al. 2012), the whaling station on Deception Island (1906) (Hacquebord 1992), the Jeanne d'Arc whaling station (1908) on Kerguelen Island (Le Mouël 2004), and the whaling stations at Husvik (1910), Stromness (1912), Grytviken (1904), and Leith Harbour (1909) on South Georgia (Basberg 2004). The investigation of these sites has generally involved the recording of the above-ground evidence in order to establish the functions of the various parts of the whaling stations. At Kerguelen Island archaeology accompanied the restoration of a number of buildings at the Jeanne d'Arc whaling station, while the whaling stations on South Georgia were investigated for their functional relationships to one another in an industrial archaeological context.

A notable component of the maritime archaeological record of the Southern Ocean and Antarctic is the presence of numerous shipwrecks which relate to all phases of the discovery and exploitation of the region. Despite the considerable number and importance of such archaeological sites, very few shipwrecks have been investigated in this region, and no scientific underwater archaeological investigations have yet taken place. In the Auckland Islands 11 ships are historically recorded as being wrecked, only 1 of which has been the subject of archaeological attention (notably, the wreck of the *Rifleman* sunk in 1833 was destroyed by salvage in 1996). The 56-ton schooner *Grafton* was wrecked in 1864, and in 2003 a small section of the vessel's hull timbering, found above the tide mark, was recorded and two timber samples taken and subsequently analyzed (Dingwell et al. 2009; Petchey et al. 2015). The most famous Auckland Island shipwreck is that of *General Grant* which sank in 1866 reputedly with a cargo of gold bullion and as a result has been the target of many salvage expeditions, fortunately, none of which has been successful in locating the wreck. Archaeologists, however, have had more success in recording the various castaway depots, boatsheds, and finger posts found throughout the Auckland Islands. In 2007 an expedition to Campbell Island mapped and took samples from two maritime artifacts described as most likely being from an unknown shipwreck that predated the known history of the island (Judd 2007). The subsequent report to the New Zealand Historic Places Trust outlined the possible origins for such material and stresses the need for further research of the maritime archaeology of the island. At least 12 shipwrecks are known to have occurred at Macquarie Island, none of which has been relocated. During an expedition to the island in 1988, archaeologists took 65 samples from exposed, partially buried, and buried timbers from around the island including the remains of sealers' huts (Townrow and Nash 1990). The analysis of these samples revealed that much of the timber excavated from sealers' huts came from the remains of the ships wrecked around the island providing insights into the postdepositional processes affecting these sites.

Archaeology on the Antarctic mainland began in the late 1960s with a focus on the conservation and preservation of huts and shelters associated with the Heroic Age of Exploration. A number of scholars have completed exceptional studies of aspects of Antarctic and Subantarctic maritime history, archaeology, and heritage assessment. For an overview of maritime sites located within the Antarctic regions, see Headland (2009). For a review of archaeology in Antarctica, see Harrowfield (2005). For current work, see the IPHC website.

Sea level change and coastal erosion provide opportunities for underwater recovery of materials associated with heroic expeditions. During the 2010 Mawson's Huts Foundation expedition, a combination of a low tide and receding ice revealed four fragments from the tail section of a Vickers REP Monoplane near Boat Harbour adjacent to Cape Denison. This "air tractor" was the

first brought to the continent as part of the 1911–1914 Australian Antarctic Expedition. Mawson's Huts Foundation staff began surveying in 2008. Terrestrial ground penetrating radar and magnetometer surveys were conducted in 2009 and 2010, and future investigation is planned (Henderson 2010; Lucas et al. 2011).

Key Issues/Current Debates

Key issues with maritime archaeology in the Southern Ocean and Antarctic regions are project funding and design, managed growth of cultural tourism, cultural heritage in relation to environmental protection, and interpretation of relevant legislation. To date, all proposed projects to survey for submerged shipwreck sites have been unsuccessful. In the 1990s, the University of Zaragoza and the Chilean Antarctic Institute attempted to fund underwater archaeological research to locate the shipwrecked vessel *San Telmo*, lost after reaching the Antarctic mainland in 1819 (Zarankin and Senatore 2005). Numerous private and public entities in Australia and the United Kingdom have attempted to fund expeditions to search for Shackleton's lost vessel *Endurance*. Expedition costs for Antarctic expeditions are well above the funding threshold for most humanities-related projects, and so far, no grants to fund underwater archaeology on the Antarctic continent have been successful. Private sponsorship has also failed to provide the funds needed to survey and recover materials from a southern marine environment. With the introduction of research vessels such as the Australian CSIRO ship RV *Investigator* – which is rated to Southern Oceans and can accommodate up to 40 scientists – more opportunities arise to "piggyback" a small maritime archaeological project on an existing Southern Ocean or Antarctic scientific voyage.

Cultural tourism in Antarctica is an ever-expanding market. The Antarctic mainland is a short 2-h flight from South America, and cruise ships regularly run to the Subantarctic Islands from Australia, NZ, and Argentina. General guidelines for Antarctic visitors (Resolution 3) were adopted at the 2011 Antarctic Treaty Consultative Meeting that recommends a "take only pictures, leave only bubbles" approach to terrestrial heritage tourism in Polar Regions. However, limited access as protection for maritime heritage located within Polar Regions should not be seen to stand alone as a viable method of in situ preservation. Cultural tourism in Antarctica is advised by the International Association of Antarctic Tour Operators (IAATO). Most heritage tourism operators place emphasis on a mix of heroic exploration and natural scenery; downplaying the role of whaling and sealing operations or addressing sites as relics of past negative behaviors (Basberg 2008). IAATO also regularly contributes to heritage funding projects.

Current interpretation of Annex III of the Madrid Protocol places emphasis on "cleanup" of the Antarctic environment. In certain cases, this can lead to negative impacts on the cultural heritage, a perception of artifacts as rubbish, and a need to include cultural resources as part of the environment (Pearson 2004; Evans 2007; Evans 2011). In 2003 and 2004, vessels *Petrel, Dias*, and *Albatros* were re-floated, emptied of oil, and *Dias* and *Albatros* beached as part of a major environmental cleanup at Grytviken, South Georgia; the station had previously been closed to tourism as a result of asbestos and oil concerns (Basberg 2004). Limited funds prevented further conservation or restoration; the vessels are now managed by the South Georgia Heritage Trust.

International Perspectives

Under the Antarctic Treaty System, the Antarctic continent is internationally legislated and managed. However, as with the islands in the Southern Ocean, all sites should be protected under relevant national legislation – as long as the claimant nation has adequate cultural heritage legislation. For example, all Australian Antarctic Territory (AAT) cultural heritage sites are protected under Commonwealth Heritage legislation and the *Environment Protection and Biodiversity Conservation Act* (as amended 2003) which also require that conservation and management plans be drafted for heritage places. This would include

submerged cultural heritage as protected under the Commonwealth *Historic Shipwrecks Act* 1976 or blanket protection to all shipwrecks over 75 years located within territorial waters up to the continental shelf.

Prior to UNCLOS, Antarctic territorial seas were only recognized to extend to three nautical miles from the coastline. Extension of territorial seas to the UNCLOS defined territorial limit of 12 nautical miles *can* be seen as a violation of the Antarctic Treaty (although all claimant nations have since extended their territorial waters to the full 12 nm limit). Continental shelf claims of 200 nm were asserted by Australia and Chile prior to the Antarctic Treaty – although only Argentina and France have made post-treaty claims to further land. EEZs have been claimed by Australia, Argentina, and Chile, mostly for fisheries purposes. The EEZ extension was not recognized under international law until 1961 – after the ATS was formed – and may also be considered a violation of the treaty. Exploitation of the "Area" (commonly used to define international waters) may be an issue as a result of overlapping territorial EEZ claims. If the Area begins at 60° south latitude, then all waters between this mark and the Antarctic convergence could be seen to fall outside the Antarctic Treaty area and relevant jurisdiction. Any cultural heritage sites located within this area may not be protected if there is no recognized EEZ claim.

Only nationals and their vessels are subject to laws mandated by their parent nation within "proclaimed waters" – as few of the other claimant nations or non-Treaty nations recognize rival claims. The United States and Russia consistently deny that any nation has territorial rights to any portion of the Antarctic landmass – although both nations have established research stations in both claimed and unclaimed Antarctic territory. Argentina, Chile, and the United Kingdom have overlapping claims. Attempts to resolve this dispute in 1956 resulted in a stalemate – as both Argentina and Chile refused to acknowledge the jurisdiction of the International Court of Justice.

With unresolved overlapping claims in the balance, investigation of known and unknown submerged sites within Antarctic waters could become an issue – if territories with overlapping claims were to disagree as to dispensation of heritage materials. However, bilateral agreements are a possibility for the "common heritage of mankind" approach international exploration of submerged heritage in Antarctic waters, in line with the original aims of the ATS.

Future Directions

Recent research has shown that there is a high probability for locating shipwrecks in Antarctic waters. Some territory nations have oversight bodies in place: Australia, New Zealand, and the United Kingdom have programs in place (Antarctic Heritage Trust [NZ], Australian Antarctic Division, Antarctic Heritage Trust [UK]), while others do not: Argentina, Chile, France, and Norway of these three have instigated investigations for shipwreck sites in Antarctic waters (*Aurora*'s anchor, *Endurance, San Telmo*), and all have instigated some heritage conservation programs and provided for management of maritime cultural sites (including whaling and sealing sites, shipwrecked timbers, and abandoned vessels) located on the mainland and associated islands. What has yet to take place in Antarctica or the Subantarctic Islands is the "traditional" maritime archaeological project – the full-scale investigation of a submerged shipwrecked vessel.

Recent efforts are focused on the development of archaeological best practice principles for polar archaeology projects. The Antarctic Treaty System is currently assessing the management of Historic Sites and Monuments, and the International Polar Heritage Committee convened a Polar Archaeology Working Group in 2017 with the aim to develop polar archaeology principles and an accompanying set of guidelines.

Standard archaeological best practice has moved away from full-scale excavation as a first option. However, Antarctic waters are an untapped resource, nominally protected, and provide an excellent opportunity to use current best practice to regulate future investigation of underwater cultural heritage. In 2010, a Parks Canada team located the HMS *Investigator* – lost while

searching for Sir John Franklin's exploration vessels HMS *Erebus* and HMS *Terror* – in Mercy Bay, offshore from the Aulavik National Park in the Arctic Ocean. Local Inuit knowledge led Parks Canada discovered the wreck of HMS Erebus in 2014 and Inuit knowledge led to the discovery of HMS Terror soon thereafter (2016). Britain transferred ownership of the vessels to Canada in 2017. Research conducted by Parks Canada demonstrates the feasibility of deep-ocean and diver-based shipwreck investigation in the Polar Regions (Parks Canada 2017).

Southwest United States and Northwestern Mexico: Geography and Culture

Stephen H. Lekson
University of Colorado, Boulder, CO, USA

State of Knowledge and Current Debates

The Archaeological Southwest

The Southwest region (Fig. 1) reflects colonial history perhaps more than Native prehistory. The ancient Southwest is seen as a cultural "island" related to, but distant from Mesoamerican civilizations – much like colonial New Mexico vis-a-vis old Mexico. The ancient Southwest was "simpler" than Mesoamerican civilizations, avoiding their complicated political histories. In the received view, modern Pueblos tribes of Arizona and New Mexico are essentially unchanging; thus, Pueblo practices of the nineteenth century can be readily transposed onto ancient sites. That view of the Southwest was crafted in large part by American cultural entrepreneurs in the early twentieth century, building on the work of early archaeologists who sought to link exotic ruins (e.g., cliff dwellings) to modern Pueblos, rather than to vanished Aztecs (the then-popular view). *Continuity in isolation* underwrote Southwestern archaeology through most of the twentieth century.

It has become clear, however, that the ancient Southwest had a diverse and dynamic history, much like human history everywhere. This entry is based on *A History of the Ancient Southwest* (Lekson 2009), which presents a recent reading of that history. Due to editorial limits, detailed citations and extended arguments supporting this

Southwest United States and Northwestern Mexico: Geography and Culture, Fig. 1 Map of the Southwest. Four quarters defined by the Mogollon Rim and old Highway 666, which approximates the Continental Divide. The northeastern and northwestern quarters correspond to Anasazi or Ancestral Pueblo; the southwestern quarter to Hohokam; the southeastern quarter to Mimbres Mogollon

entry will be found in that volume. References here identify recent major synthetic works, some of which propose alternate readings of the ancient Southwest.

Southwestern archaeology has enjoyed remarkable investments of funds, energies, talents, and public recognition for a relatively straightforward archaeology (Fowler 2000). Many sites remain clearly visible; preservation is generally excellent; and tree-ring dating provides cheap and accurate chronology. After 1960, large Cultural Resource Management (rescue) archaeology projects in the Hohokam and Anasazi regions have far surpassed academic research; CRM data are fundamental to our understanding of these areas (Roberts et al. 2004).

In recent years, archaeology has attempted to work more closely with indigenous Pueblo and other Native groups in the Southwest, with mixed results. Many collaborations are successful, but Native views of history are sometimes at odds with archaeological data. That conundrum confronts archaeology globally; the Southwest may be a place where these cultural and intellectual challenges can be usefully explored and, perhaps, resolved.

The Region and Its Nomenclature

Most of the Southwest is too dry for farming. Yet many areas were farmed, through chancy rainfall farming (aptly termed "dry farming"), or with more reliable canal irrigation from streams and rivers. The key subsistence crops included maize, beans, and squash; cotton was grown at lower elevations. Large game included elk, deer, pronghorn, mountain sheep and, on region's eastern boundary with the Great Plains, bison. Rabbits and small mammals were eaten, especially when large game resources were hunted out; and domesticated turkey substituted for game in some times and areas. Turkeys and dogs were the only domesticated animals.

Two geographic lines quarter the region (Fig. 1). An escarpment called the "Mogollon Rim" runs roughly from west to east, separating the higher Colorado Plateau (hereafter, Plateau) on the north from the lower Deserts to the south. A line along old Highway 666 (and roughly approximating the Continental Divide) separates western and eastern Plateaus, and western and eastern Deserts.

Archaeological "cultures" correspond roughly to those quarters: Anasazi (or, Ancestral Pueblo) Culture developed on the Plateau, with significant differences east and west. The Western Desert corresponds to the Sonoran Desert and the Hohokam Culture, with its core in the Phoenix Basin. The Eastern Desert corresponds to the Chihuahuan Desert and two key Mogollon Culture districts, Mimbres and Casas Grandes. Upland Mogollon societies occupied the mountainous Rim.

The Early Agricultural Period (1500 BCE to CE 400)

Maize arrived from western Mesoamerica well before 2000 BCE (Staller et al. 2006). Maize spread rapidly through the four quarters of the Southwest, but the relatively small cobs of early maize did not transform the region (Vierra 2005). Five centuries passed before farming villages took root in the Western Deserts around 1500. New strains arrived, perhaps together with new people from the south, already committed to agriculture. It took special knowledge to grow maize – originally a tropical crop – and to adapt it to new settings. Irrigation was necessary as maize moved from wetter to drier climes. Desert farmers planted first in naturally wet bottomlands (*cienegas*) in the Eastern and Western Deserts. As favored settings filled, farmers created new fields by diverting water from streams through small ditches to terraces above the floodplain.

Knowledge of maize may have been embedded in social structures, ceremonial practices, political relationships, and languages: a Uto-Aztecan mother stock that later became Piman, Hopi, and other Southwestern languages (Hill 2006; see also Merrill et al. 2009). A chain of Uto-Aztecan-speaking groups linked the Western Deserts and West Mexico. Shared histories ensured that desert communities looked south throughout the following centuries.

The Early Agricultural period in the Southwest was part of a much larger, continental phenomenon: from Poverty Point in the lower Mississippi

Valley to Olmec in Veracruz, North American was waking up. Villages in the Western Desert, by 1000 BCE, consisted of 20 or more small, shallow pit structures – family homes – around a plaza. Near the center of some villages stood a single large building, a place for community affairs. Defensive sites such as Cerro Juanaqueña (1250 BCE) – a large village on an impressively terraced and walled mountain in the Eastern Deserts – attest to frictions in the Early Agricultural period. Its massive terrace walls were the Southwest's first monumental construction.

Boom times in the Deserts: Uto-Aztecan speakers spilled up over the Mogollon Rim and on to the Plateau. The indigenous peoples of the Plateau – people (presumably) speaking languages that would become Zuni, Keres, and Tanoan – noticed the thriving villages around Tucson and the terraced mountain of Cerro Juanaqueña. Small canals were constructed around Zuni as early as 1000 BCE. But early maize did not prosper on the Plateau. When maize-based villages finally appeared on the Plateau, they probably owed much to the Western Deserts, perhaps a final push of Uto-Aztecan migrations around 500 BCE. The Western Desert people moved north onto the western Plateau, displacing Plateau natives to the east (LeBlanc 2002). The divide between the Uto-Aztecan west and the Zuni–Keres–Tanoan east cast long shadows. Many centuries later, hierarchical governments would rise in the east, among the "locals," but not among the peoples of the west, who harked back to different, desert ways.

Brownware pottery spread throughout both Deserts and the Plateau between CE 200 and 400. Its initial appearance, in the Deserts, may hark back to the South – there must have been constant comings and goings between the Deserts and West Mexico. A brownware "foundation" formed across the region, a craft shared among villages with different histories and backgrounds. After mastering the basics, potters invented techniques and created styles increasingly characteristic of each area. By CE 500, different traditions marked the Plateau (graywares), the Western Desert (buffwares), and the Eastern Desert (brownwares).

Maize fueled southwestern civilizations, but in fact, the Southwest was a tough place to grow maize. Maize's failures were as important as its successes. The mismatch between maize and the Southwest played out in unequal production, agrarian tensions, droughts, famines, and – above all – the many measures, social and political, taken to support maize-based societies in blistering deserts. Most importantly: canal irrigation systems in the Western Desert. It is not so much that maize worked in the Southwest; it is that *they made it work* – most of the time.

Early Villages (CE 400–750)

By about CE 400, more than a millennium after farming villages first appeared in the Deserts, a few hundred small settlements flanked small steams, irrigating crops with small, simple ditches. Three short centuries later, the western deserts were crossed by a dozen massive canals systems – main canals 10 m wide and up to 30 km long, hundreds of distribution canals, intakes, drains, etc. – taking water from major rivers, the Salt and the Gila. Western Desert irrigation was the largest canal system in North America. Small farming villages grew to become very large towns. The remarkable increase in scale probably demanded new political structures, or perhaps new political structures allowed larger village sizes, or a bit of both. New political practices replaced the older, inclusive village-council level of governance.

New ways of living in the Southwest reflected, distantly, a new idea in North America: urbanism at Teotihuacán, far to the south. It was not the first Mesoamerican city but Teotihuacán was by far the greatest. Teotihuacán redefined the possible. No one in the Southwest had to "invent" villages, towns, or cities. Every wandering hunter-gatherer, far into the northern tundra, was at least dimly aware that people could live in densely packed, permanent cities.

The Desert farming villages succeeded and grew. Small, simple ditches got deeper and longer, bringing water out to upper terraces to meet the need for new farmlands. Irrigation – even on these modest levels – demanded centralized decision making, a few making decisions for the many.

Southwest United States and Northwestern Mexico: Geography and Culture,
Fig. 2 Community House at Las Capas, Early Agricultural Period site, near Tucson AZ

Around CE 500, at larger villages, a few prominent families with more lands, more wealth, and more power built notably larger residences ("Big Houses") which incorporated ritual features. A ring of multiple Big Houses were built around and immediately adjacent to the central plaza (Fig. 2). Other families built their smaller houses behind the inner circle of Big Houses, farther away from the plaza. The council houses of earlier times disappeared, their governance functions evidently shifting to Big House families. Importantly, the half-dozen Big Houses in each village appear to be equals: no one Big House bigger than the others.

Big House political power was modest, scaled to small, early ditches – insignificant by Mesoamerican measures. When irrigation tapped larger rivers – the Gila and the Salt rivers in the Phoenix Basin – the scope of decision making expanded exponentially. Canals got big and Big Houses got bigger, at towns/sites today called Snaketown, Grewe, and a score of others in the Phoenix Basin. Their spheres of interest and control surely expanded beyond farming and irrigation.

At Snaketown and Grewe, leaders legitimized themselves with exotic objects, badges of office: copper bells and other Mesoamerica regalia. Big House leaders may have traveled to the source, to western Mexico and Mesoamerica, returning with these impressive objects. It seems likely that people to the far south knew of the fertile farmlands, impressively irrigated, of the Western Deserts. People on the Plateau doubtless noticed too. Plateau villages of any size were few and far between and relatively impermanent – short lived and semi sedentary. Plateau farmers discovered that, unlike the Deserts, it was possible to farm away from streams, relying on precipitation: rainfall farming. Rainfall farming was risky, but it reshaped life on the Plateau, for both the Uto-Aztecans of the west and the local populations of the east. The two groups were increasingly difficult to tell apart, but the old divisions remained in language and history.

Plateau peoples had not yet developed centralized political institutions. Decisions were probably made in a large community or council house: the "Great Kiva." Great Kivas were round chambers, often roofed but sometimes not, and big enough for representatives of families or clans to meet and make decisions, presumably in the context of ritual.

Unlike Desert farming, tied to canal systems, rainfall farming required no investment in infrastructure and therefore no commitment to any particular place. Rainfall varied from year to

year and place to place. Groups moved often, on cycles of a generation or less – a fluidity that discouraged political leadership.

Yet, in the end, leaders put themselves forward. Perhaps inspired by desert Big House elites, ambitious Plateau families apparently decided to try it too. In the Deserts, political leaders lived in Big Houses prestigiously near the plaza. And at a few Plateau villages around 500 – such as the remarkably large Shabik'eschee site in Chaco Canyon – the first attempts at political leadership appeared as exceptionally large pit houses, built near the village center and the Great Kiva – much like Desert Big Houses.

Big House-manqué elites at Shabik'eschee and other Plateau villages were not needed to control and coordinate canal systems. Indeed, they may not have been *needed* for any economic or agricultural reasons. Tensions between the eastern and western Plateau may have promoted political leadership. Remarkable things – perhaps alarming things – were happening in Western Deserts, marked by Big House elites. Western Plateau villages had historical and linguistic ties to the deserts. But the East did not. Eastern Plateau societies might have needed (or accepted) tighter organization, but political leadership did not "take" on the Plateau. Unlike canal communities of the deserts, Plateau families – if annoyed by would-be leaders – could simply leave, move to a better or at least different place. Rainfall was equally spotty everywhere. If a leader became obnoxious, the led could leave.

It was different in the Deserts. People were tied to canals – the investment in infrastructure created true sedentism. Canals were essential for farming, so leaving was not an option. Consequently, Desert towns got bigger and bigger; towns in both Western and Eastern Deserts spanned centuries, compared to a generation or two on the Plateau.

Canals on the Salt and Gila rivers created a breadbasket, the richest farming economy in the Southwest. The confluence of those two rivers was the setting, a thousand years later, of the modern city of Phoenix – which "rose from the ashes" of the ruins of the earlier Desert civilization. Phoenix had maize adapted to irrigation, long-growing seasons, abundant water from the rivers, canal technologies to capture that water, and a Big House political system to make it all work. Deserts farming economies needed leadership. Phoenix at 700 was a civilization waiting to happen. The region was primed to produce the food surpluses needed to fuel great things: kings, empires, whatever. But Big House rulers did not become kings. Desert civilizations took a different path.

Hohokam (CE 750–900)

Hohokam, as a set of practices, began around 700 perhaps with another wave of people, or a new wave of ideas from western Mesoamerica, drawn by the thriving irrigated farmlands of Phoenix. The ideology united many groups – newcomers, long-settled migrants, and converted locals. It was a supra-governmental or anti-governmental or instead-of-governmental ideology that united large areas and many (perhaps ethnically distinct) people, and got big things done – all without kings.

In the Phoenix core of the Western Deserts, Hohokam presented new ways of life manifested as oval, earthen ball courts (Fig. 3), elaborate (but largely democratic) cremation burial rituals, bold new styles of art, and, apparently, decision-making structures that disguised or diffused political power (Gumerman 1991; Fish and Fish 2007). As at Teotihuacán (but on a far smaller scale), individual political leaders in Big Houses were replaced by a government of bureaus and committees – in the guise, perhaps, of priesthoods and councils. For a few brilliant centuries, Hohokam ideologies allowed an enormous, elaborate irrigation economy without evident centralized political power – and propelled a remarkable cultural explosion out from Phoenix and across the deserts.

Some elements of what became Hohokam already existed in the deserts, part of the continuous interchange from the deserts to western coastal Mexico and back again. Some parts of Hohokam were endemic, local developments. But the key elements were new to the Deserts, introduced almost certainly from the south. Hohokam ideologies replaced and overshadowed

Southwest United States and Northwestern Mexico: Geography and Culture, Fig. 3 Ball court at Wupatki, near Flagstaff AZ

conventional Big House leadership (which remained for few more centuries at the village level).

It seems fair to say that people *became* Hohokam. Perhaps the most conspicuous and widespread markers of Hohokam were bracelets or more likely armlets of *Glycimeris* shell. Bivalve shells from the Gulf of California were carefully shaped into armlets and sometimes carved with symbols – birds carrying snakes, desert toads, and the like. They had once been rarities, but after 700, they were ubiquitous. People in every sizable settlement had this badge of membership prominently displayed on an upper arm.

Inward-facing clusters of three or four shallow pit houses, around a small courtyard, formed the typical home – in both the Western Deserts and in northern Mesoamerica. A dozen or two dozen courtyard clusters were grouped into small neighborhoods or "village segments." Multiple neighborhoods encircled a large plaza which, as in earlier periods, marked the center or core of the villages. Ball courts displaced Big Houses as the iconic architecture, the key monument. Not *re*placed: Big Houses and their elite families continued, but their leadership functions were transferred, apparently, to another arena. The whole village could witness the ball "game" that (as in Mesoamerica) probably played out political issues, territorial dilemmas, and difficult decisions. Each village of sufficient size had a ball court; large villages had two, usually at the edge of town, away from the old central plaza (Wilcox 1991).

Around the central plaza was a ring of low earthen mounds, usually round or oval. Mounds were architecture: A site was selected, fill was brought in and sculpted to shape, and a smooth plaster surface applied. Might these be Big Houses, elevated? No evidence has been found of houses atop these mounds, but most have been trenched as "trash mounds," not excavated as architecture. But, on the evidence, these mounds were not residential. They were relatively low – waist-high, well below the peaked roofs of surrounding houses. These low mounds supported ceremonies and small presentations, presumably performed for comparatively large audiences. The village could view actions or performances atop the mound's elevation, like a stage. Mounds were inclusive; events that would be restricted in the old community house or private in Big Houses were now public.

Hohokam did not emphasize elite individuals or families. Not a return to village councils – Hohokam society was probably far too large and complex for that – but rather a decentralized, inclusive stew of ritual, power, and decision making. Individuals surely had power, but they did not flaunt it with Big Houses, palaces, or tombs.

Whatever Hohokam was, it controlled individual political ambitions and curtailed social stratification and hierarchy.

To the south, it was a time of kings and nobles – the Epi-Classic, and the beginning of an age of city-state polities (*altepetl*, in Nahua) and, later, empires. The fall of Teotihuacán (about 550/600) sent ripples – tsunamis – of political power outward, ruling houses looking for places to rule (Nelson 2000). Displaced noble families transformed towns throughout Mesoamerica into small city-states. The aftershocks of Teotihuacán's fall reached the Pacific Coast with the temple-towns of the Aztatlan horizon and reached the very northernmost frontiers of Mesoamerica at La Quemada.

Petty chiefs and Big House leaders must have been tempted to emulate southern kings. As Mesoamerican polities popped up nearer and nearer to home, they provided models of hierarchy. Hohokam apparently rejected seventh- and eighth-century Mesoamerican political models – while using a wide range of Mesoamerican forms and symbols.

For almost three centuries, Hohokam worked. More than worked: Hohokam prospered and expanded – exploded – out from Phoenix in one of the most remarkable events in the history of the ancient Southwest. Ball courts, distinctive pottery, and burial rituals pushed rapidly upstream, up to the very edges of the Plateau. Surprisingly, Hohokam did not go far downstream, stopping at Gila Bend a short distance west of Phoenix.

By 900, there were hints of hierarchy not within but between and among towns, with the largest occupying positions of control at the heads of canal systems. A geographic pecking order emerged. The very largest towns, such as Snaketown, Grewe, and Aztatlan, had the very largest ball courts.

One of the largest ball courts was built at Pueblo Viejo, high up the Gila River, 250 km east of Phoenix. Beyond Pueblo Viejo, Hohokam elements reached deep into the Mimbres region of the Eastern Deserts, where mountain streams flowed out of the Mogollon highlands into the Chihuahuan Desert (Nelson and Hegmon 2010). Mimbres settlements were initially less permanent than the villages of Western Deserts. Pit house groups moved from one valley to the next, allowing depleted soils, hunted-out game, and gallery forests to replenish and regrow. It was a successful way of life – so successful that rising numbers filled the valleys.

Like the Hohokam societies of the Western Desert, Mimbres farmers dug ditches to water their fields. They almost certainly learned the tricks of irrigation from Hohokam, but Mimbres canals were modest compared to the huge Phoenix systems. Mimbres accepted, selectively, Hohokam beliefs: cremation burial (for some), ideologically charged naturalistic designs on pottery, and – conspicuously – Hohokam *Glycimeris* armlets. Not every Mimbres person wore them, but some were buried with dozens.

Canals pinned Mimbres villages in place. Pit houses, which had a fairly short use-life, stacked up (insofar as pit structures can stack). Newer houses cut into older abandoned structures. Some villages grew large, with several scores of houses – untroubled, it seems, by hierarchy (Hegmon 2002). Much like Hohokam, Mimbres ideologies discouraged conspicuous leadership. Mimbres, however, did not accept the whole Hohokam package; ball courts, essential to Hohokam, were absent. Instead, Great Kivas (a form shared with Plateau pithouse villages) held communities together, serving some of the purposes that ball courts played for Hohokam.

Hohokam reached as far north as east. Western Plateau peoples and Phoenix shared linguistic and historical connections – so deep (by this time) to perhaps be mythical. Hohokam ball courts were built far north in the western Plateau, in the dormant volcanic fields west of Hopi.

With increasingly sophisticated knowledge of land and maize (and decades of favorable weather), Plateau populations grew and villages got larger (Reed 2000). Over generations, people became accustomed to the structures and strictures of village life. They had to: There were fewer open valleys, fewer places to start over – and, thus, more possibilities for hierarchical leadership. Inter-village squabbles escalated after 700, reaching levels approaching warfare by

850. Increasing violence called for leaders, to lead or to avoid war.

Over the short term, shifting rainfall favored some areas over others. In the ninth century, rains fell on the great Sage Plains, northwest of Mesa Verde and population concentrated there. Towns expanded, and lasted longer (Lipe et al. 1999; Noble 2006). There, ambitious families built the first Big Houses on the Plateau since the false start at Shabik'eschee, three centuries before.

Basic house forms had changed, somewhat, since the pit houses of Shabik'eschee. Plateau peoples now used more stone masonry in their architectural repertoire. Behind the pit structure (which remained the primary living space), they added a small masonry building of a half-dozen low rooms used mainly for storage. With food and gear housed safely above, the pit structure itself could be smaller and easier to heat. That combination – six rooms and a pit structure – became the standard for Plateau housing (and a clear contrast to the courtyard homes of the Western Deserts). The new, ninth- and tenth-century Big Houses used that same form: six rooms and a pit house modules, built *really* big: *Great Houses*.

Great Houses – Big Houses by another name – were essentially residences, built on the same ground plan as other houses, but larger, more substantial, and built with greater craft and care. Just like the early Big Houses of the Western Deserts, Plateau Great Houses combined secular and ritual architecture in conspicuous, even (modestly) monumental elite residences. Both Desert Big Houses and Plateau Great Houses were, importantly, *houses – not* public facilities like ball courts or Great Kivas.

Great Kivas – the people's council chambers – continued to be built, especially in villages evidently lacking Great House elites. One village might have a Great Kiva but no Great House. Another might have a notable Great House but no Great Kiva. Often both were present but at some distance apart. It seems likely that Great Kivas were buildings of the people, while Great Houses were buildings of elites.

Great Houses eventually appeared over much of the Eastern Plateau. The Western Plateau stayed out of it, for a while. In western villages, homes were often jammed together in long rows. Each home was essentially identical to the next. Those villages often (usually?) had Great Kivas. Eastern villages were more dispersed, with clusters of freestanding homes or scattered short segments of three or four conjoined homes. Large settlements had scores of these separate housing segments and one or more Great Houses – and no Great Kiva. The people were architecturally fragmented, without a common hall or communal center. Looming over them, the Great House offered the coherence and regulation needed, perhaps, for village life.

Plateau peoples still moved, shifting villages as they had for centuries, but in larger groups and longer cycles than in earlier times. Rising violence urged safety in numbers. Elite lineages – noble families – probably emerged as important families maintained their status from old village to new village, from one generation to the next. They may have begun to think it was their right, or their duty, to rule.

Chaco (CE 900–1150)

The decades from 900 to 1150 were momentous in North America. Three centuries of uncertainty and reorganization that followed Teotihuacán's fall ended with the rise of Tula and the beginning of Mesoamerica's Post-Classic Period (950–1500; Smith and Berdan 2003), an era of small polities and long-distance interactions. Mesoamerica was dotted with hundreds of city-states. Short-lived "empires" encompassed multiple city-states, but not until the Aztecs (in the Late Post-Classic) was empire-building truly successful. Yet the Early Post-Classic was notable for long-distance trade and interaction – ideologically charged "international" styles of pottery and architecture that linked cities that are a thousand kilometer apart. In eastern North America, the great city of Cahokia urbanized the middle Mississippi Valley and set the course for subsequent political history, much as Teotihuacán had set the agenda for Mesoamerican urbanism five centuries before. Cahokia was larger than most Post-Classic Mesoamerican cities.

On the Plateau, Great House families had several generations to become accustomed to

their status and duties – not unlike Mesoamerican noble families. Great House families moved south of the San Juan River and into Chaco Canyon. Perhaps Chaco was simply the last empty, isolated valley. Perhaps Great House leaders saw themselves as the heirs of Shabik'eschee. At any rate, the people who promoted Great Houses at Dolores and Blue Mesa – their direct descendants or their spiritual heirs – built three Great Houses in Chaco Canyon by 900. Unlike earlier, short-lived Great Houses, these lasted. After a century-long germination, Chaco burst forth to dominate the Plateau from 1020 to 1125 (Noble 2004; Lekson 2006).

Pueblo Bonito was the largest Chaco Great House, a giant "D"-shaped building with massive sandstone masonry walls standing up to five stories tall. Its 600-plus rooms and enclosed plaza covered almost one hectare. It appears that perhaps a dozen or so families (presumably extended families) lived at Pueblo Bonito. They were very important families: elite or noble families. And much of the building was not residential, as was the case at most Great Houses. Chaco's Great Houses were in part elite residences and in part monuments. Eventually, eight major Great Houses were built at Chaco, presumably representing eight elite or noble lineages. Planning, coordination, and labor rivaled Phoenix canals. There was an important difference between Desert canals and Plateau Great Houses: Canals delineated an economy; Great Houses manifested an ideology of power.

Great House families lived privileged lives. They probably did not farm or hunt – maize and meat were brought into Chaco. They probably did not make pottery or chip arrowheads or grind maize. Those too were imported into the canyon. They probably traveled far to the south (almost certainly to Mimbres and very likely to western Mexico and Mesoamerica) and brought back macaws, metals, cacao, and other wonders (see, e.g., Crown and Hurst 2009). When they died, they were buried with pomp and ritual in the oldest parts of the building (Akins 1986; Plog and Heitman 2010), becoming part of its history. Great Houses were the houses of generations of elites – noble families of the Plateau. Or so they might have seen themselves, modeling their polity on the Mesoamerican *altepetl* – or city-state, the ubiquitous political formation in Mesoamerica during Chaco's era, translated into Plateau idioms, architectures, and cosmologies.

With the rise of noble families at Chaco, the people found themselves redefined as commoners. Villages with dozens of separate individual homes – six rooms and a pit house – dotted the landscape. Set on a low hill or prominence above the village stood a small, secondary Great House, and off among the commoners' homes a Great Kiva – the traditional community center of the people. The two forms coexisted, perhaps uneasily, throughout Chaco's reign.

Chaco created a degree of political integration over most of the Plateau, offering economic and political security. Escalating inter-village violence ended with Chaco's rise (LeBlanc 1999). And there was the fact of the Hohokam. Plateau peoples must have known of the remarkable Hohokam expansion of 750–900. Western Plateau peoples shared (distantly) a language with the Desert civilization. Eastern Plateau peoples remembered the earlier Uto-Aztecan expansion onto the Western Plateau. On some level, Chaco itself may have been a geopolitical response to Hohokam.

Chaco's success was in part a gift of geography and climate. Chaco Canyon itself was a dry and cheerless place, unfit for extensive agriculture, but it was central to a ring of villages, 80–150 km from the capital, around the better-watered margins of what would become Chaco's interior region. Chaco, from its beginnings, served as a center for the interior region, evening out the short-term agricultural problems of surrounding villages. Bulk goods – building timbers, pottery, maize – moved freely within that 150-km radius. Many things came to Chaco and stayed there, in the service of the elites. Maize moved into and through the canyon, perhaps from places that had plenty to places that had none.

Chaco's influence soon reached far beyond that original region. Colony or copy Great Houses popped up, up to 250 km away. Local leaders almost everywhere on the Plateau joined with or deferred to Chaco. And it worked – ultimately,

about 150 second-tier Great Houses marked Chaco's greater region (Kantner 2003). They represented local, second-tier elites or noble families who undoubtedly acknowledged and visited Chaco, perhaps regularly, on a network of "roads" radiating out from, and in to Chaco Canyon.

Chaco Canyon itself was decidedly top-heavy – a city of palaces – but the tip of the social pyramid was in fact rather small: perhaps a thousand or fifteen hundred elites. And the pyramid had a broad base: tens of thousands of commoners across the wide Plateau. At a guess, commoners numbered perhaps 40 or 50,000, about the same size as a Mesoamerican city-state, but spread over a much larger region.

As Chaco waxed, Hohokam waned. The high water mark in the deserts came between 900 and 1050; on the Plateau between 1020 and 1250. In the decades after 1000, Hohokam's remarkable expansion reversed and shrank back in on the Phoenix Basin. The hallmarks of Hohokam civilization – ball courts, shell insignia, elaborate cremation burials, low mounds, and (most importantly) polity without kings – continued into the early 1100s, but the energy was gone. Most ball courts fell out of use. Hohokam fragmented into multiple local polities. Phoenix and Tucson went separate and unequal ways.

Even in decline, Hohokam remained far more impressive as an economic landscape than Chaco – or anything else, then or thereafter, on the Plateau or the Rio Grande. The canal systems continued to expand, bringing more of the desert under cultivation. Each canal system was apparently independent, with key social dynamics among multiple settlements strung along the same canal. A dozen independent "irrigation communities" emerged within the Phoenix Basin, and the Hohokam ideology ensured that power was diffused within those communities. Hohokam political life – and social life – was relentlessly modular (Abbott 2000).

Population in the Phoenix towns increased, less from local growth than from in-migration into Phoenix. Thousands of people retreated from the edges of the Hohokam world back into the heartland. The demographic implosion accelerated through CE 1300 (Abbott 2003). With all those new people, the farmlands of Phoenix were perhaps reaching their limits.

Mimbres, in the Eastern Deserts, registered the shift from Desert to the Plateau, like a weather vane swinging to the winds. Mimbres pit house villages once looked west to Hohokam; after 1000, they looked north to Chaco. Pit houses were quickly replaced by small masonry homes of a half-dozen rooms, not unlike the Plateau house form, and spectacular black-on-white pottery (Fig. 4) (Hegmon 2002; Shafer 2003). Something like Great Houses, 400 km from Chaco, were built at a few villages, with much larger rooms, more formal layouts, and more massive masonry than was customary in Mimbres pueblos.

Would-be Great House elites never took hold. Through a remarkable combination of old Hohokam ideologies, new Plateau forms, an influx of Mesoamerican ideas, and their own local genius, Mimbres people developed new ways of living that allowed for large towns, complicated canal systems, and interactions with the Chaco world – but that avoided Chaco's hierarchies and political complications.

Going around Hohokam, Mimbres villages evidently established direct trade relations, over the Sierra Madre, with western Mexico and perhaps even the Aztatlan cities of Mexico's Pacific Coast. Mimbres had a straight shot down the east

flanks of the mountains to the Post-Classic states of central Mexico.

Mimbres middlemen supplied Plateau rulers. Long-distance trade shifted from the Pacific side of the Sierra Madre to the inland side. Inland routes pioneered by Mimbres reached their fullest expression with the rise, two centuries later, of Paquimé.

Chaco prospered. Then, 300 km west of Chaco Canyon in the western Plateau, a wonderful awful thing happened. A volcano erupted, at the northernmost edge of the Hohokam world and westernmost reaches of Chaco. Sunset Crater was a small volcano, but it was spectacular (Elson 2003; Downum 2012). Its plume of fire was visible from highpoints on the Eastern Plateau – possibly from Chaco – and from Phoenix. The volcano became an important place, perhaps more important than Chaco Canyon.

An extraordinary collection of structures and monuments converged at the volcano's flank, at a safe distance: Wupatki. The place was known to Chaco; a small Great House there preceded the eruption by perhaps a decade. After the eruption, a larger Great House rose after 1135. (By then, Chaco was gone and Aztec Ruins was ascendant on the Plateau.) Wupatki had elaborate turquoise artifacts, macaws, and Mesoamerican objects that rivaled Chaco and eclipsed Aztec. And more: at Wupatki, a Great Kiva was built next to a large masonry-walled Hohokam ball court, perhaps the last ball courts ever built. Chaco and Hohokam met, at last, under the volcano. But by 1135, when Wupatki was built, Hohokam was greatly diminished and Chaco Canyon was at its end.

Chaco ended with political strife. The orientations of major Great Houses marked two competing cosmologies. The old, original worldview (of 850 and perhaps even earlier) was represented by a loose southeastern (solstitial?) alignment. A newer, tighter north–south (cardinal?) cosmology was introduced at several Great Houses around 1020. A crisis may have come around 1070, with the construction of a new capital far to the north at Aztec Ruins. The location of the new Chaco was fixed by cardinal direction: due north, up the Great North Road, to the San Juan River. About 1110 construction began at Aztec Ruins. Its plan was profoundly solstitial. It seems that the cardinal party prevailed in the location of the new capital, but the solstitial bloc determined the new capital's form and cosmic vision. The cardinal noble families quite possibly turned away from Aztec, and reversed directions, going south (Lekson 1999).

Retrenchment and Reorganization (CE 1150–1300)

The cosmological schism – manifest as solstitial versus cardinal – had real political consequences. Aztec was, literally, only half the capital that Chaco had been (Lekson 1999). And its region was reduced to less than half of Chaco's. Aztec's polity, however, included Mesa Verde and, more importantly, the densely settled Great Sage Plains of southwestern Colorado (Noble 2006; Lipe et al. 1999; Varien and Wilshusen 2002).

Things that worked at Chaco failed at Aztec. The new capital was unable to keep the peace or to bring the rain, as Chaco had done. A major drought hit from 1135 to 1180 – a drought, while Wupatki flourished! A second burst of monumental construction at Aztec marked a brief rebound. But by about 1250, rainfall became erratic and unpredictable. Violence spun out of control. Farmsteads – previously scattered freely among their fields – clustered into large, walled towns or huddled together in alcoves high on the cliffs of Mesa Verde (Fig. 5), defensive patterns seen across the Plateau (Adler 1996).

To enforce its failing rule, Aztec unleashed lethal force (Turner and Turner 1999). At farmsteads, squads of warriors fell upon families failing in their tributary duties. Men, women, and children were brutally and publicly killed and left to rot, unburied, in the ruins of their homes. But even terror could not hold together.

It was a classic case of unintended consequences. Aztec's use of force apparently drove away already-wavering groups. Beginning as early as 1220 (decades before the "Great Drought" of 1275–1300), villages began leaving Aztec's troubled region. Movement and

Southwest United States and Northwestern Mexico: Geography and Culture, Fig. 5 Cliff Palace, Mesa Verde CO

relocation had always been typical, but within the confines of the Plateau. Now, people moved farther, setting off cascades that rippled out from the Plateau into the Deserts.

Aztec and its region were abandoned, an exodus of tens of thousands of people, complete and permanent, seldom paralleled in human history. A final "Great Drought" from 1275 to 1300 was merely the final punctuation on a story already told – most people were already gone. Only a few of their descendants returned as pilgrims praying over ancestors, never to reestablish villages or farms.

Most who left the Plateau went to the southern fringes of Chaco, the regions of modern pueblos: Hopi, Zuni, Acoma, Laguna, and the many towns of the Rio Grande, spiking Pueblo populations around 1325 (Adams and Duff 2004). Some went farther: whole villages relocated far to the south in the East and West Deserts. In the west, Mogollon pueblos and Hohokam towns grudgingly accepted newcomers. Migrants sometimes settled atop defensive buttes and mesas. A generation later, they were joined by more people from the north, following paths into the upper Gila and the Salt drainages. These newcomers integrated into fading Hohokam societies – on their own terms.

The old order passed. Chacoan nobles, perhaps, and Chacoan ideas of hierarchy survived Chaco and Aztec's fall. Chaco lineages in the deepest south (beyond Acoma and Zuni) maintained their status decades after Chaco removed to distant Aztec. Perhaps, to commoners, Chaco was always a remote, near-mythical place – Rome to an ancient Pict, Jerusalem to a medieval serf. In any event, southern elites kept up appearances, brooding in their Great Houses on hills above their towns. The second wave of immigrants – who knew what was really happening

up north and wanted no more Great Houses – drove those relic elites out, and south.

Authority vanished, refugees arrived, and violence ensued. Two centuries of Chacoan peace ended after 1175. Fighting quickly escalated to village-on-village warfare. As in the Mesa Verde region, scattered farmsteads clustered into larger and larger villages. But unlike those in the north, southern villages were not hodgepodge affairs. They were carefully planned, with the organizing principles of Chacoan architecture applied to thousand-room pueblos, with tall perimeter walls laid out as precise squares and circles. Homes in-filled those geometric spaces in a jumble; but within those impressive walls, no single house was "great." From the Rio Grande on the east to the mountains of central Arizona on the west, aggregated towns employed elements of Chacoan planning but rejected Chaco-style ruling elites.

We do not know the fates of the northernmost elites – the lords of Aztec and their allies. Not all who died in the violence of the thirteenth century were commoners. What of the southern Great House leaders, elites, and noble families around Zuni and Acoma? Their lives were disrupted first by the end of Chaco, then by the fall of distant Aztec, and finally by a popular movement – literally a migration – away from hierarchy and toward a new social order. Some elites surely converted; many moved. North – a region and direction of ill omen – was no longer possible. There was no one left to rule. To the south, Hohokam beckoned from the deserts – a civilization without kings.

The causes of warfare on the Plateau did not obtain in the Deserts, but refugees from the violence brought the means and perhaps the disposition. The revival of defensive *trincheras* communities (massively terraced hills) in the twelfth and thirteenth centuries reflects cracks in the tottering Hohokam edifice. For many generations, Hohokam ideologies supported diffuse governance, collaboration, cooperation – at least, no obvious rulers. Desert dwellers lacked clear leaders who could react quickly and decisively. Hohokam institutions could not turn the violence spilling out of the Plateau – or displaced Plateau noble families looking for someplace to rule.

Architecture tells the tale. For centuries, Hohokam homes were loosely clustered in small courtyard groups, and those groups into open neighborhoods. The pervasive modularity of these units reflected the nonhierarchical nature of Hohokam society. By about 1150, the modular house clusters were replaced by adobe walled "compounds": enclosing pueblo-like houses built of puddled adobe. In marked contrast to the open house clusters, compounds were closed, rigid, exclusive spaces. That architectural development (inspired at least in part by Plateau building traditions) marked the breakdown of the old Hohokam way of life (Fish and Fish 2007).

Ball courts – the *sine qua non* of Hohokam – were replaced, around 1150, by platform mounds (Fig. 6). The old courts were not leveled or razed; they were simply forsaken, left open and unused. The contrast between the sunken surfaces of ball courts and the raised surfaces of platforms was a clear indication of new ways of doing business.

Nor could platforms be confused, architecturally, with the earlier Hohokam mounds. In contrast to the low, rounded mounds – which had served as stages for public viewing of ceremonies and rituals – the new platform mounds were large, tall, sheer-sided, and sharply rectangular structures. Some platforms – square, massive, controlling – were built directly over earlier low mounds, making a statement. The height of the platforms lifted their upper surfaces (and the buildings and activities they supported) far above the people. People below could see figures only at the platform's edge – criers, priests, those who reported, ordered, and communicated. Events at the center of the platform were effectively screened from public view. Priests and leaders did their work above and beyond ordinary people's reach. Platforms were the architectural antithesis of both earlier low mounds and ball courts – both of which allowed many to see the activity or performance. Platforms paralleled the shift from open courtyard groups to closed compounds. Something had changed in Hohokam thinking. Indeed,

Southwest United States and Northwestern Mexico: Geography and Culture, Fig. 6 Curtis Site platform mound, near Gila Bend AZ

"Hohokam," as a suite of beliefs and practices, effectively ended.

Hohokam fell apart just as Plateau populations spilled into the deserts, into the upper reaches of the Gila River and Salt River. On the upper Salt River (and perhaps elsewhere), massively walled, small, rectangular masonry buildings were built in existing towns. They had no precedent in the deserts – perhaps distant variations on the Great House theme? But the desert peoples did not want Great Houses. Tonto Basin quasi–Great Houses were quickly converted into rectangular platform mounds – filled with rocks and capped with a flat adobe surface. The old Hohokam world, for at least a few decades, fended off Plateau adventurers and displaced nobility.

While Hohokam shifted shape, Mimbres went through parallel changes. It was probably no coincidence that when Chaco's move to Aztec was complete and construction at the old center ceased around 1130, Mimbres societies rejected, completely, the ideological and political forms that had held them together for a century. The change was sudden and complete – as if someone had thrown a switch. Once-bustling Mimbres towns emptied. Mimbres pottery – for a century, the focus of intense artistic energies, depicting scenes of myth and history – became anti-designs: black, burnished interiors, dimly reflecting the viewer's eyes and nothing more. The people formerly known as Mimbres changed how they built their homes – from stone masonry to puddle adobe, usually at new towns some distance removed from the old pueblos. Many Mimbres people moved up into the hills and declined; others probably moved north and joined the big towns around Zuni and Acoma (see also Gregory and Wilcox 2007). But most Mimbres apparently moved south, out of their valleys and into the desert.

New adobe towns with black burnished pottery were built where there were no permanent streams – just dry desert channels. With no streams, there were no canals. It is not entirely clear how people supported themselves – at small cienegas, perhaps, a throwback to the very earliest farming villages. These short-lived post-Mimbres settlements skipped from valley to valley in a fast-tempo dance. When the music stopped, around 1250, many probably came to rest in the valley of the Rio Casas Grandes, 100 km south of the Mimbres Valley. They apparently became part of the base population, the commoners of the Southwest's last and greatest city, Paquimé.

Not only a push from the north, but a draw to the south: the Middle Post-Classic of Mesoamerica (Smith and Berdan 2003). Tula fell by about 1150. The implications of that fall are a matter of debate: truly momentous or merely

legendary? In any event, with Tula's end, the Post-Classic pattern came into focus in vibrant clarity: expansive politics, long-distance dynamics, power plays and upheavals, and a swirling world of migrations, invasions, expulsions, and fragmentation into even more small city-states. That was the world the Southwest knew, of which it was a part.

Paquimé (CE 1250–1450)

The influx of migrants fleeing the troubled north strained the existing Pueblo communities at Hopi, Zuni, Acoma, and the Rio Grande. Violence flared. Wars broke out, with villages sacking other villages. Larger towns were safer but – without rulers – inherently unstable and often split apart. How to hold together big towns? Native histories suggest that no one wanted the kind of leaders who had created cities like Chaco and Aztec. New ideologies rose and old ideologies were revived to replace political power with ritual authority. The explosion of ideas is reflected in art. The older, Chaco-era, grimly geometric black-on-white pottery gave way to a polychrome revolution. Unprecedented pigments, dynamic symmetries, and new icons mirrored changes in worldview and cosmology (Fig. 7). Images of kachinas and new supernaturals bloomed on pottery and rock art like flowers after rain (Schaafsma 1994, 2007; VanPool et al. 2006). After several centuries of experiments – competing cults and cures – the foundations of modern Puebloan society emerged from the crucible of post-Chaco chaos: communal, egalitarian, ritually based, purposefully antihierarchical.

Southwest United States and Northwestern Mexico: Geography and Culture, Fig. 7 White Mountain Redware, c. CE 1350. UCM 9634. (Courtesy University of Colorado Museum of Natural History)

Chaco faded to a (bad) memory. For many Pueblos, Chaco and Aztec became White House, remembered as a great city led by rulers who, improperly, had power over other people. White House was a lesson: It came to a bad end, with violence, famine, and forced migration. For Navajo people who lived later in those same lands, Chaco was remembered as a place where a kinglike ruler – neither Navajo nor Pueblo – enslaved all the peoples of the region and forced them to build palatial homes for his family. In this history, the people rose up and overthrew the tyrannical rule.

New town plans and new iconography reflected new ways of living. But the larger picture remained grim. Regionally, population began to fall sharply after 1300 and continued to fall for several centuries. Paradoxically, fewer and fewer people jammed into bigger and bigger towns (Adams and Duff 2004). Several towns might group into a defensive alliance or cluster. Clustering put safe distances between battered populations – de facto demilitarized zones. The frequency of violent incidents declined, but not their severity. Wars still raged between villages, between clusters.

The Plateau's trouble accelerated Hohokam's transformation, but on the opposite tack – away from faceless bureaucracies and toward more visible hierarchy (Fish and Fish 2007). Large areas within the old Hohokam sphere emptied as people retreated back into Phoenix, taxing the diminishing productivity of those long-farmed lands (Abbott 2003). At the largest Phoenix towns, health suffered. Most babies died; those who survived died young. The old Hohokam way of life was gone, the intricate web of beliefs abandoned or discredited. New forms of governance were needed to stem the downward spiral.

Out on the margins of the old Hohokam world, there were out-of-work rulers: Great House nobles

pushed off the Plateau. In the upper Gila and the Tonto Basin, local people had earlier rejected Great Houses, filling their rooms with rocks and rubble and converting them to platform mounds. Would-be rulers, either from the north or inspired by the north, riposted by building new houses – Great Houses – atop those same platforms. Great Houses rose from platform mounds along the Desert–Plateau borderlands, and soon after in the Phoenix heartland and the Tucson Basin. Elites had come to the deserts.

Just as platform mounds were built over earlier low mounds, Great Houses atop platform mounds were a blunt architectural statement, a stratigraphy of power. Pima people who live today amid the empty ball courts and eroding mounds of Phoenix and Tucson recall in their histories the elites who lived atop platforms. They were foreigners, even supernatural – certainly not Piman. They came into the heartlands and imposed their rule, tyrannical and oppressive. But the new regime could not reverse the social and economic decline. The people suffered under these rulers for a time and then rose in revolt. They went from platform mound to platform mound, killing the kings. The Pima stories ring true. Something like a class revolt toppled the new governments.

The drought of 1135–1180 marked the end of Chaco. The Great Drought of 1275–1300 closed the book on Aztec. The Phoenix Basin's bitter end was punctuated by huge floods on the Salt River in 1357–1359 and again in 1381–1384 (Graybill et al. 2006). Equally disastrous floods hit the Gila River in 1420. These floods destroyed the canal systems. After centuries of decline, the heartlands were unlivable.

Plateau and Pueblo peoples took themselves out of the Post-Classic world. One Eastern Desert, society more closely engaged the south. Paquimé rose on the Rio Casas Grandes, in the southern Eastern Deserts, while Pueblos jelled and Hohokam fell. Prior to Paquimé, the Casas Grandes Valley had been a quiet backwater with a scattering of pit house villages (for another view, see Whalen and Minnis 2001, 2009) – the southern margin of the densely populated Mimbres region.

A century later, by 1250, the Mimbres valleys were empty and the Rio Casas Grandes teemed with people – in large part Mimbres peoples, shifted south through a string of short-lived desert town. They knew the Casas Grandes Valley and would have recognized that it was perfect for irrigation, but in their desert hegira, they probably lost the technical skills to tap the large river. The remarkable ideologies that had united Mimbres villages for major public works, such as canals, had been left behind, dramatically rejected a century before. If large populations were to live on the Rio Casas Grandes, major irrigation would have to be grafted into the valley – lock, stock, and barrel.

New towns on the Rio Casas Grandes surely sought help from the West, perhaps from experts fleeing Phoenix. But Hohokam canal irrigation was an intricate balance of enormous public works administered by deliberately diffuse governance, fine-tuned to Phoenix Basin societies. It might be possible to transfer technology, but not that administrative culture (even then on the skids in its homelands). Neither Hohokam nor Mimbres had traditions and institutions of strong central leadership. In the Southwest, Chaco (and its successor, Aztec) had those skills. Chacoan elites knew how to get big things built. They dug canals at Aztec Ruins, their final Plateau capital. And the heirs of Chaco and Aztec Ruins nobility – or at least its cardinal factions – were conveniently available.

Pueblo histories tell us that, after the fall of White House, the people were instructed to go south, (in part) to find macaws. Most stopped at Acoma, Zuni, and other pueblos. But others continued straight south beyond the arc of modern pueblos, in search of macaws (we are told). If they continued south, they probably proceeded through the empty Mimbres Valley, once Chaco's source for macaws and other regalia (Lekson 1999).

Native peoples in southern Chihuahua told Spanish conquistadors of two large groups coming into the region from the north, led by two brothers. The brothers found an old hag perched on a huge iron boulder. At this omen, one brother

Southwest United States and Northwestern Mexico: Geography and Culture, Fig. 8 Paquimé (aka Casas Grandes) in northern Chihuahua, Mexico

stopped to found a city. The second brother and his people continued south. An exceptionally large, boulder-sized iron meteorite was found at Paquimé. Was that the omen? Paquimé became a famous breeder of macaws, on commercial scales.

The people who became the modern Pueblos voted with their feet against hierarchy – by moving away from Aztec and by *not* moving on to Paquimé. But many northerners joined the journey to the south. The late thirteenth/early fourteenth century saw extraordinary population increase in Chihuahua – a combination of local populations, Mimbres migrants, Plateau northerners, and other peoples attracted to the new city from south and west. The region became one of the most densely settled areas in the Southwest. Paquimé was a new and brilliant city (Fig. 8) (Di Peso 1974).

Many architectural and organizational details – for example, the verticality of multistoried Great Houses – recalled Chaco, Aztec, and the now fabled cities of the north. Paquimé was constructed of poured adobe, a desert technology adopted by Mimbres people in their wanderings after they had ceased being Mimbres. Adobe was a poor fabric for Paquimé's towering five-story walls. Form trumped function – or, rather, symbolism trumped compressive strength. The city was an aggregate of separate, multistoried compounds, each the scale of an old Chaco Great House. The compounds were palatial – expansive and expensive and filled with treasures. Around the urban core were platform mounds and masonry pyramids, at least three I-shaped masonry ball courts (direct copies of Mesoamerican models, not the peculiarly Hohokam earthen ovals), and, most remarkably, monumental effigy mounds, unique in the Southwest. At least two of these, a four-armed cross and a long north–south snake, commemorated cardinality.

Paquimé was more closely tied to Mesoamerica – both west and central – than any previous southwestern polity. Architectural forms – colonnades, ball courts, and (modest) pyramids – and astonishing quantities of ideologically charged Mesoamerican objects far surpassed Chaco, Mimbres, and Hohokam. While all three southwestern traditions played parts in Paquimé, the city's leaders redefined (or refined) themselves as truly Mesoamerican nobility – not Chaco's wannabes. Southern objects and architecture were no longer simply props or window dressing, reinterpreted in local contexts for local politics.

Paquimé and Phoenix were "peer polities" – one on the way up, the other on the way down. Paquimé undercut Hohokam's commerce. The Plateau's demographic center of gravity shifted dramatically east to the Rio Grande (Adams and

Duff 2004; Kohler 2004; Powers 2005; Schaafsma 2007), well away from Hohokam's established trading circuits, but a straight shot north for Paquimé. Phoenix's western sphere was reduced to Hopi – its linguistic cousin – and a dozen large but short-lived towns in the Mogollon uplands that soon were abandoned, one after the other. Paquimé had an up market and Phoenix did not. By 1450, little was left of Hohokam's earlier glories, save stories and histories.

Pueblos and Others (CE 1450–1600)

Paquimé fell, sacked by unknown parties shortly after 1450, the last episode in the political history of the Southwest. The densely populated Casas Grandes region emptied. Some may have gone to Hopi or other Pueblos, but many survivors did not return to the north. They probably went west over the mountains to the Rio Sonora, or followed factions gone south centuries earlier. The people who came out of Casas Grandes could not have been the Mexica Aztecs, who founded their empire in 1427. Rather, southwestern peoples were sub-currents in a vast swirl of migrations, mostly north to south, which created a complex patchwork of northern and western Mesoamerican societies later conquered by Spain.

Population continued to plummet over the entire Southwest. The number of towns decreased. Whole districts were depopulated. Scores of towns – big towns! – in the Western Deserts, in the Mogollon uplands, and along the southern Rio Grande were abandoned a century before Spanish conquistadors entered the region in 1540.

The Pueblos from Hopi to Taos absorbed new peoples, not always of the same language or history. The unsettled social conditions must have tempted Pueblos (and Pueblo individuals) to reassert a degree of political authority, to bring order out of chaos. There are hints, even today, of that kind of authority in Rio Grande Pueblos. But the bitter lessons of Chaco and Aztec were still fresh. After 1300, Pueblos avoided political hierarchy and suppressed would-be leaders through a complex mesh of ritual and social practices. In one researcher's words, they "defeated hierarchy" (Mills 2004).

The fifteenth century saw renewed trade with Mexico, almost certainly tied to the fall of Paquimé, which had controlled inland trade routes. Turquoise was still much in demand in Late Post-Classic Mesoamerica. The eastern Pueblos also forged economic connections to and across southern Plains groups (Adams and Duff 2004).

The people who would become Navajos and Apaches arrived from the north, after the fall of Chaco and probably after the end of Aztec – but not long after. Athabaskan speakers may well have been on the Plateau during Aztec's reign. Navajo clans have detailed knowledge of the times and places of the ancient Plateau cities.

Piman peoples recovered slowly from the final, tumultuous centuries of Hohokam and their rebellion against the platform mound rulers. It would take deserts many years to rebound from centuries of intense canal irrigation, overhunting and overgathering, and the depletion of firewood and other resources. Before they could revive completely, Europe arrived.

Coronado's army entered the deserts in 1540, looking for cities of gold. The memory of a rich, urban Southwest lived on in the stories of Mesoamerican traders. Traders guided conquistadors into what should have been the new Mexico. The stories were true: There had been cities, rich cities. But the Spaniards came a century too late for Paquimé and the Phoenix Basin, two centuries too late for Aztec and Chaco. The pueblos they found were nothing like cities: no gold, no wealth, no commerce, no kings. Discouraged, the conquistadors returned to Old Mexico. Sixty years later, Don Juan de Oñate returned with colonists seeking not cities but farmlands and metals. They stayed. Not without incident of course: Native revolts, political revolutions, Yankee invasions, and all the alarms and excursions of modern history.

The history of the ancient Southwest ends at 1600. After 1600, the Southwest was no longer Native, no longer aboriginal, no longer "ancient." Native people remained, of course, and their stories continued in the face of crushing colonization.

Key Issues in Southwestern Archaeology

Recent research has greatly clarified Chaco (e.g., Lekson 2006) and Hohokam (e.g., Fish and Fish 2007) – two key episodes in Southwestern archaeology. The nature of Hohokam governance pre-1150 remains enigmatic; indeed, what was "Hohokam," as a cluster of beliefs and practices? A horizon of great importance recently emerged with the Early Agricultural Period (Vierra 2005). Agricultural societies (we once thought) began around CE 200 in the Deserts and CE 500 on the Plateau, but now we know that farming towns began a millennium earlier in the Deserts. Equally important are new research and new understandings of the Casas Grandes region in the Chihuahua Desert. In an understudied area, interpretations vary remarkably. One school sees Paquimé (Casas Grandes) as relatively small and local (e.g., Whalen and Minnis 2001, 2009); another school follows the site's original excavator (Di Peso 1974), emphasizing Paquime's role in the larger Post-Classic world (Riley 2005; Lekson 2006). Early Agriculture and Paquimé "bookend" Southwestern prehistory: the first farming villages and the last great city. While many other key questions remain in the Southwest, Early Agriculture and Paquimé stand out as epochal events – as yet, far from fully understood.

Sowunmi, Margaret Adebisi

Emuobosa Akpo Orijemie
Department of Archaeology and Anthropology, University of Ibadan, Ibadan, Nigeria

Basic Biographical Information

Prof. M.A. Sowunmi (nee Jadesimi) is known to many as both a botanist and an environmental archaeologist. But it is in palynology that she is a household name in Nigeria. In fact she is the country's foremost palynologist and environmental archaeologist (archaeobotanist).

Prof. M.A. Sowunmi was born on September 24, 1939, in Kano, Northern Nigeria, where her father, Revd (later bishop), had been posted to pastor the northern province of the Church of Nigeria (Anglican Communion). The young 'Bisi was admitted into the Department of Botany, University College Ibadan (now University of Ibadan) in October 1959 and graduated B.Sc. (Special Botany) (Lond.) in June 1962. She was awarded a University of Ibadan Postgraduate Scholarship in October 1963 to undertake Ph.D. research work in palynology. At that time, because palynology was not taught in Nigeria, 'Bisi had to be sent abroad. So in April 1964 she travelled to Stockholm, Sweden, and spent six months studying palynology in the laboratory of Prof. Gunnar Erdtman, the *Father of Modern Palynology* (Sowunmi 2004). Her Ph.D. work was supervised by Prof. Erdtman. On July 27, 1967, M. Adebisi Sowunmi earned a Ph.D. (botany) degree from the University of Ibadan. She thus became the first Nigerian to obtain such a degree.

In December 1967, at the instance of Prof. Thurstan Shaw, the doyen of archaeology in Nigeria, she was appointed as a postdoctoral research fellow at the Archaeology Unit of the Institute of African Studies, University of Ibadan; she held this position until his unfortunate death in 2006. When she became a lecturer in the newly created Department of Archaeology (now Archaeology and Anthropology), University of Ibadan. She became Professor of Palynology and Environmental Archaeology in October 1982 and officially retired from the University of Ibadan in 2004, having attained the statutory age of 65 years.

Prof Adebisi Sowunmi was a visiting professor at the Department of African Archaeology, Uppsala University, Sweden, from October 1 to December 23, 1997, and visiting professor at the Institute of Archaeology, University College London, England (January 4 to March 23, 1998). Between April and June 1998, she was a visiting professor at the Departments of African Archaeology and African Archaeobotany, Johann Wolfgang Goethe-Universität, Frankfurt am Main, Germany. She has travelled to at least 23 countries to attend scientific conferences, meetings, and workshops. She is a member of several international organizations, such as the Archaeological Association of Nigeria (member, Board of Trustees), Palynological Association of Nigeria (Foundation and current President), Science Association of Nigeria (life member), West African Archaeological Association (past president), World Archaeological Congress, International Association of African Palynology, Nigerian Environmental Study/Action Team, and the Nigerian Field Society. Prof. Sowunmi has published 31 scholarly papers in scientific journals, four books, ten chapters in books, and six technical reports and delivered over 30 public lectures and conference papers.

Major Accomplishments

Prof. M. Adebisi Sowunmi, having been awarded a postgraduate scholarship by the University of Ibadan (1963–1967), became the first person to earn a Ph.D. degree in Botany from the University of Ibadan, Ibadan, Nigeria. She pioneered the paleo-ethnobotanical and environmental archaeology research in Nigeria and the university palynological research with the

setting up in 1971 of the first Nigerian University Palynology Laboratory. The laboratory contains over 3,600 reference pollen slides of present-day Nigerian and some other West African plants; albums of original descriptions, hand-drawn diagrams, and photomicrographs of the pollen grains important Nigerian plants; and 151 overhead transparencies covering various topics in palynology, Nigerian and West African archaeology, and environmental archaeology. Prof Sowunmi supervised the second Ph. D. in botany (palynology) and the first Nigerian Ph.D. in environmental archaeology (with Dr. Phillip Allsworth-Jones) in 1981 and 1991, respectively.

She (with Kogbe, C.A.) was the first to indicate the age and paleoenvironment of the Gwandu Formation (Continental Terminal), Northwestern Nigeria. With two others she produced the first descriptions of some Eocene pollen of the Ogwashi-Asaba Formation, Southeastern Nigeria. She published the first paper on the Late Quaternary vegetation and environmental history of Nigeria and the pollen morphology of extant Nigerian plants which are ecological indicators. Prof. Sowunmi also carried out the first pollen analysis of honey from the forest and savanna zones of Nigeria, obtained the first botanical evidence of the beginning of agriculture in Nigeria, made the first pollen analysis of an archaeological site in Nigeria (with E.O. Awosina), and indicated the relevance of archaeology in national development.

In January 2003, M.A. Sowunmi was conferred with an honorary Doctor of Philosophy degree in the Humanities by Uppsala University, Uppsala, Sweden, in recognition of her outstanding scholarship and contributions in research and teaching in the fields of environmental archaeology and paleobotany (Sowunmi 2012). In July 2005, she was one of the keynote speakers (long-term and short-term socio-environmental dynamics in West Africa: the challenge of environmental archaeology) at the Pan African Association for Prehistory and Related Studies Conference, Gaborone, Botswana.

During her academic career at the University of Ibadan, she produced seven Ph.D.s and over 20 M.Sc.s. She was involved in the supervision of Ph.D.s in the Department of Archaeology and Anthropology, University of Ibadan, from 2007 till February 2013. Prof. Sowunmi returned to teaching, being an adjunct lecturer for one undergraduate course, three M. Sc. courses, and the supervision of two M. Sc. research projects in the Botany Department, University of Ibadan. It is of common knowledge that Sowunmi is a feminist (Folorunso 2004) and has a high degree of intolerance for indolence. She is reputed to be an exceptionally thorough and effective teacher (Egunyomi 2004). At Ibadan and elsewhere, she has taught palynology, paleobotany, environmental archaeology, and ethnobotany. She is revered as the Matriarch of Nigerian Palynology and preaches that to be a good palynologist, one must think, dream, and feel pollen.

Prof Bisi Sowunmi's husband was late Prof. Segun Sowunmi, and they have three children and one grandchild.

Space Archaeology

Alice Gorman
Department of Archaeology, Flinders University, Adelaide, SA, Australia

Introduction

Space archaeology is the study of the material culture associated with space exploration from the twentieth century onwards. This includes terrestrial infrastructure related to the development, manufacturing, operation, and use of space systems, spacecraft and space debris located throughout the solar system and the landing sites of robotic and crewed missions on other planets and celestial bodies. Space archaeology sits within the field known as "archaeology of the contemporary past."

The era of modern rocketry, which created the first real capacity to break free of Earth's gravity, had its roots in the amateur rocket societies of the first half of the twentieth century. In World War II (1939–1945), Germany developed missiles capable of reaching other continents and, hence, also capable of reaching space. The V2 rocket drew on the expertise of the amateur rocketeers such as Wernher von Braun, and following the war, a diaspora of German rocket scientists and materials seeded the space industries of the nascent spacefaring nations.

Four rocket test and launch sites were established in 1947: White Sands (USA), Woomera (UK/Australia), Kapustin Yar (USSR/Kazakhstan), and Colomb-Béchar (France/Algeria). While these were all military sites, the first satellite launches occurred against the backdrop of international cooperation for the International Geophysical Year of 1957–1958. In 1957, the USSR successfully injected the aluminum sphere Sputnik 1 into Low Earth Orbit. Within the emerging Cold War, the demonstration of superior ideology through space technology became a central feature.

Within six years, the rapid growth of technology enabled the USA to launch the first telecommunications satellite into geostationary orbit, about 35,000 km above the Earth. This ushered in the era of modern telecommunications. Telephone and television were now able to achieve global coverage using just three satellites, as predicted by legendary science fiction writer Sir Arthur C. Clarke in 1945. The "space club" expanded as more nations across the world began to develop their own industries, as both suppliers and consumers of space services.

The landing of humans on the Moon in 1969 captured the imagination of the world. However, this remarkable achievement had less impact on terrestrial life than the developing industries of telecommunications, navigation, meteorology, and Earth observation, provided by an ever-evolving population of satellites in Earth orbit and their ground infrastructure. Nonetheless, the series of Apollo lunar landings between 1969 and 1972 made humans active agents in shaping an interplanetary cultural landscape (Gorman 2005a).

With over 7,000 spacecraft launched since 1957, there is a growing population of space hardware in the solar system, with most of it located in Earth orbit. In the twenty-first century, private and commercial space enterprises are in the ascendancy, and space tourism is poised to become a major industry. The study of this distinct technology and its social correlates has the potential to offer new insights into contemporary life on Earth.

A Brief History of Space Archaeology

Turning the archaeological gaze on space exploration is far from a recent development. In 1967, historical archaeologist James Deetz suggested that one day archaeologists would look at spaceships as part of the archaeological record. In the late 1990s, William Rathje (1999) extended his investigation of the role of garbage in contemporary human society to include orbital debris. Around the same time, NASA funded the Lunar Legacy Project, for which Beth Laura O'Leary (2009) and her team created an archaeological inventory of the Tranquility Base lunar landing site, where humans first set foot on another celestial body in 1969.

The first decade of the new millennium saw interest in space archaeology gain momentum. Gregory Fewer (2002) explored issues surrounding the protection of historic planetary landing sites on the Moon and Mars, proposing a system of heritage listing. Alice Gorman (2005a, b, 2009a), in her study of orbital debris, proposed a cultural landscape approach to space and applied the Burra Charter (1999) heritage management guidelines to spacecraft in orbit in order to understand their cultural significance. She also highlighted the impacts of space industry on Indigenous people through the location of launch sites on their lands, configuring launch sites such as Woomera and Kourou in French Guiana as places of cultural contact and exchange. Robotic landing sites on Mars were considered by Dirk Spenneman (Spennemann & Murphy 2009). The *Handbook of Space Engineering, Archaeology, and Heritage* (Darrin & O'Leary 2009) provides a comprehensive overview of the entire field.

With India and China planning human missions to the Moon, determining appropriate management strategies for Tranquility Base became more urgent, and O'Leary and others spearheaded a successful campaign in 2010 to have artifacts at the site registered at state level in the USA, preparatory to a nomination for the World Heritage List. In 2011, NASA responded to the growing awareness of lunar heritage issues by creating a set of guidelines for future missions. Both the World Archaeological Congress (WAC) and the International Council on Monuments and Sites (ICOMOS) have recognized that space heritage is a distinct area requiring consideration.

Definition

Characterizing the Archaeological Record in Space and Time

Space archaeology deals with human physical and material interactions with microgravity, technology, and interplanetary environments. Gravity regimes very different to those on Earth have a profound structuring effect on the distribution of space artifacts throughout the solar system. The material of space archaeology could be divided into several zones, all connected to the surface of the Earth through launch and tracking sites:

- Earth (terrestrial infrastructure, terrestrial and marine orbital debris reentry sites)
- Earth orbit (Low Earth Orbit, Medium Earth Orbit, geosynchronous and geostationary orbit, Molniya orbit, Sun-synchronous orbit, and various others)
- Cislunar space (the region of space between the Earth's atmosphere and the Moon)
- Lunar orbit and surface
- Heliocentric orbit (around the Sun)
- Venusian orbit and surface
- Martian orbit and surface
- Miscellaneous orbital, landing, and encounter sites
- Interplanetary space

The Earth orbits are most dense in material, with over 19,000 trackable spacecraft and pieces of debris, from Low Earth Orbit up to the "graveyard" orbit above 35,000 km (Fig. 1). This debris includes the Vanguard 1 satellite, launched in 1958 and now the oldest human object in space. Gorman (2005a, b) has argued that orbital debris forms an organically evolved cultural landscape with value in its own right. In doing this, she has proposed a new frame of reference for archaeology, structured by gravity, rather than the

Space Archaeology, Fig. 1 Orbital debris (Image courtesy of NASA)

S

traditional division into terrestrial and celestial spheres (Gorman 2009b).

In the rest of the solar system, human material is present on the Moon, Mars, Venus, Titan (a moon of Saturn), two asteroids and a comet, and in orbit around most celestial bodies (Capelotti 2010). Of particular significance are the Martian, Venusian, and lunar sites where crewed or robotic missions have landed. Tranquility Base on the Moon, with its iconic astronaut bootprints, can be compared to the Paleolithic footprints of *Australopithecus afarensis* in volcanic tuff at Laetoli in Tanzania: both can be argued to represent evidence of major evolutionary turning points. At the farthest reaches of the solar system, there are four spacecraft, only two of which are in communication (Voyager 1 and 2; Fig. 2).

The distance from the Earth creates requirements for the ground segments, in terms of their location on Earth and the types of receiving and command antennas. The technology of spacecraft is inseparable from the infrastructure required to send and receive signals, so neither can be studied in isolation. Many early generations of launch and tracking sites are now abandoned, such as the Colomb-Béchar launch site in Algeria and the Orroral Valley tracking station in Australia (Fig. 3), overtaken by changing technology and politics. There are a myriad of satellites which are no longer functioning and other defunct spacecraft, such as rocket bodies, in Earth orbit.

Early Cold War launch sites are also frequently associated with nuclear testing, as this requires similar infrastructure and environmental conditions. In Australia, the USA, the Pacific, and other places, many of these sites are now abandoned. Rockets were originally developed as nuclear warhead-bearing missiles, and early satellites were ideological weapons in the Cold War, as Gorman and O'Leary (2007) have argued. The Cold War (1945–1991) can be regarded as the first stage of the Space Age, encompassing the "Space Race" and the "conquest" of space as matters of national prestige.

While launch sites tend to be distributed among the spacefaring states (e.g., USA, Russia, Europe, India, China, Japan) and their colonies, most countries have some level of space infrastructure, and all are now users of space-based services. Most nations maintain satellite downlink facilities, even if only at the level of domestic satellite dishes and telephones (Gorman 2009a). The cultural footprint of satellite data can also be considered as the domain of space archaeology. This is particularly so in the period from 1991 until the present, the second stage of the Space Age, when space activities are driven by the telecommunications requirements of globalized economies.

Commercial and private space enterprises, including tourism, are likely to characterize the next phase of space activities. We can expect new

Space Archaeology, Fig. 2 Voyager 2, launched in 1977 by the USA (Image courtesy of NASA)

Space Archaeology, Fig. 3 Antenna pylons at the former Orroral Valley NASA tracking station, Australia (Author's image)

forms of propulsion and new ways in which humans relate to technology. They will not arise sui generis: they will be built on the "heritage" of past space activities. Nevertheless, one can imagine a time when the spacecraft of the twenty-first century appear as quaint and outdated as a horse and cart or a biplane. Considering space exploration as an expression of cultural change invites and inspires long-term visions of the future.

Key Issues/Current Debates/Future Directions/Examples

Methods, Theories, and Applications

Space archaeology employs the same methods as historical and industrial archaeology in using survey, excavation, artifact analysis, oral history, documentary research, aerial imagery, and geographical information systems (GIS) to characterize and analyze material remains and landscapes. However, specialist knowledge in areas such as electronics, propulsion systems, telecommunications, aerospace engineering, materials science, and planetary science is required in order to recognize and record features of significance. A limitation is that usually sites and objects in orbit and on celestial bodies can only be accessed by remote sensing, and there is much that is unknown about what actually survives in these locations. Several space agencies and organizations track debris in Earth orbit within the limits of their observation and modelling capacities. Reconnaissance missions have located and filmed previous landing sites on the Moon and Mars. Less frequented parts of the solar system can only be speculated about.

Studying the material record of the contemporary past presents some unique challenges. Because we are immersed in it, we may not be the best judges of what is significant and what is not: we are implicated in the ideologies of our time and place. Theorists of contemporary archaeology speak of the necessity of making the familiar unfamiliar. Techniques used to do this often trespass into the realm of the artist, using juxtaposition, montage, performance, and changes of scale to bring into focus objects and the relationships between them that are normally obscured. Another method of historical and contemporary archaeology is the use of oral history and personal narratives to augment and stand alongside the physical material. Frequently, there is a disjunction between individual memories and knowledge and the published or officially sanctioned histories. In these gaps, we can discern something about human engagement with the contemporary past and the social memories constructed around high technology.

A significant application of space archaeology is in heritage and environmental management. While remoteness has, in the past, protected many space sites from human impacts, this is rapidly changing. For example, the level of orbital debris has now reached a critical point where it threatens functioning satellites, and plans are being devised to remove or destroy portions of it, while renewed interest in lunar, Martian, and Venusian exploration raises the question of how sites such as Tranquility Base can be best managed. Creating an inventory of space sites, landscapes, and objects and assessing their cultural significance prior to impacts arising from orbital debris cleanup, future missions, and space tourism is a priority for space archaeologists.

The Dublin Principles for the Conservation of Industrial Heritage Sites, Structures, Areas, and Landscapes (ICOMOS and the International Committee for the Conservation of the Industrial Heritage or TICCIH) provide some guidance here. The principles stress the interconnectedness of industrial places across multiple sites, from the extraction of raw materials to the systems of energy and transport. This is particularly applicable to space, where a single strand of operation can span the distance from Earth to orbit and back again across, for example, tracking stations, satellites, and downlinks. To conserve this heritage, inventories of all physical and intangible elements, including documents, objects, and landscapes, need to be made.

Since its inception, space exploration has tended to be the province of industrial elites and has been dominated by the USA and the former USSR. However, given the agenda of historical archaeology to uncover the lives of those often

overlooked in official histories, such as women, working classes, ethnic minorities, and Indigenous people, an archaeological approach to space exploration has the potential to tell very different stories than those captured in the popular account of the "Space Race." For example, Indigenous people were frequently contributors to the success of space exploration through the forced surrender of their lands for launch sites, in a form of late industrial colonialism. Rocket launch sites can be conceived as places where ongoing cross-cultural engagements and tight security requirements structured new types of cultural landscape.

In turning a lens on the contemporary or recent past, space archaeology can illuminate aspects of twentieth- and twenty-first-century human existence. Despite a general public lack of awareness of their dependency on satellite-based services such as PNT (Position, Navigation, and Timing), the capacity for global telecommunications and Earth observation has transformed personal experiences of space and time, cultural transmission and hybridization, and national and transnational economies. While it is common for historians, economists, and other scholars of the contemporary world to analyze the movement of information and capital and their cultural consequences, few acknowledge the role that the *material* culture of space plays in enabling these late industrial transformations. In this regard space archaeology intersects with Science and Technology Studies (STS) and Social Construction of Technology (SCOT) studies. Archaeology brings to the investigation of space exploration the traditional focus on material culture, deep-time perspectives, and an understanding of the resilience and flexibility of cultural responses to change.

With the world divided into spacefaring and non-spacefaring states, the United Nations has called for the inclusion of those usually excluded from space: women, Indigenous people, and "developing" nations. Space archaeology can contribute to redressing the imbalance between the haves and have-nots of space by highlighting alternative narratives accessible only through an analysis of what is left behind and discarded and the material impacts of new technologies both in space and on Earth.

Space Heritage Protection

Beth Laura O'Leary
Department of Anthropology, New Mexico State University, Las Cruces, NM, USA

Introduction

The heavens and the night sky have always belonged to humanity. Celestial bodies have been named and are present in the narratives, calendars, and rituals of the world's cultures. The Moon, especially, features in stories created by cultures from Africa to the Arctic since prehistoric times. In a real sense, everyone owns the Moon. However, it is only within the last 50 years that humans have created technology that has taken them into outer space and onto the lunar surface. Cultural resources exist on the Earth's surface, in space, on the Moon, and on other celestial bodies (O'Leary 2006: 307). There are archaeological sites, structures, and objects, both on Earth and in space, which are within an enormous cultural landscape. All are linked by humanity's extraordinary scientific achievements in space exploration. Objects and sites in space can be looked at as part of a much larger assemblage that until the Space Age – a particular time and level of technological development – were confined to Earth but then entered the archaeological record somewhere else (Staski 2009: 23).

Definition

Space Archaeology is a new field which focuses on the "material culture relevant to space exploration that is found on earth and in outer space (i.e., exoatmospheric material) and that is clearly the result of human behavior" (Darrin and O'Leary 2009: 5). It began with and is most strongly linked to the Cold War and post-Cold War period. The Cold War was played out by military, social, and political maneuvers in space as well as on Earth. In 1945, the USA and USSR engaged in a race to acquire both German rockets and rocket scientists and engineers (Gorman and O'Leary 2007: 73). The descendants of the V-2 rocket launched the first satellites and later propelled the first humans into space and onto the Moon. Apollo 8 astronaut Col. Frank Borman called the Apollo Program a battle in the Cold War (Borman 2001). These events changed history and provided the basis for the associated technologies that currently include a satellite-based telecommunication industry and spacecraft from many nations that continue to explore farther and farther away from Earth.

The term Space Archaeology is usually paired with space heritage which focuses on ways to identify, evaluate, and protect significant places and artifacts associated with space exploration that may be lost through destruction, looting, recycling, or neglect and environmental degradation. In some ways, the remoteness of, for example, sites on the Moon or Mars and the costs associated with visitation have provided a form of protection, at least from human impacts. The preservation of objects in space and on other celestial bodies is, for the most part, in a gray legal area as ownership and the varied post depositional contexts lie within zones of many contested and evolving international treaties and agreements. The goals of space archaeology and heritage are to illuminate the interaction of human behavior associated with space in order to understand both the past and the present, provide for preservation of significant sites and objects, and, perhaps, be useful for future space missions (Gorman and O'Leary 2013; O'Leary 2015).

Historical Background

The earliest behavior and material evidence for Space Archaeology begins with two astronauts. As part of the Apollo 12 mission in November 1969, astronauts Conrad and Bean were instructed to survey and record information about *Surveyor 3*, a robotic probe that had landed on the Moon's surface almost 3 years earlier (Fig. 1). Conrad and Bean landed their spacecraft 180 m from *Surveyor 3* and conducted the first "archaeological" studies on the Moon by photographing and collecting samples and returning them to Earth for analyses. Although the analyses were designed to help NASA detect changes to the materials from *Surveyor* caused by the lunar environment, Capelotti (2004: 51) notes this as the first example of extraterrestrial archaeology and "formational archaeology, the study of environmental and cultural forces upon the life history of human artifacts in space."

The Space Age is different from other periods in humanity's technological evolution, both in its speed and the global nature of the massive amount

Space Heritage Protection, Fig. 1 Apollo 12 Astronaut Alan Bean and Surveyor 3 on the lunar surface November 19, 1969. (Courtesy of NASA)

Space Heritage Protection, Fig. 2 Sputnik and Vanguard 1. (Courtesy of NASA)

of research and development by nation- states that delivered material culture to very remote regions. The Space Age usually begins with the launch of the first satellite, USSR's *Sputnik 1* in 1957, followed by the successful launch of *Vanguard 1* by the USA (Fig. 2). *Sputnik 1* remained aloft only several months after its launch, but created the first object and orbital debris which expanded the archaeological frontier into space. *Vanguard 1*, a 15.2 cm sphere with antennae weighing about 1.5 kg, was launched on March 17, 1958 and continues to circle the Earth every 2 h. It is expected by NASA to remain aloft for the next 600 years (O'Leary 2009a: 771). *Vanguard 1* is currently the oldest human object in orbit, and its orbit will allow it to be essentially preserved in space.

Space exploration is ongoing and includes many kinds of robotics. What lies at the edge of the subdiscipline is interest in the cultural heritage of robots (O'Leary 2009b: 41). Spennemann (2007) focuses on emergent heritage or technologies that are still in use and form an ongoing technological investment. This area includes heritage created by robots in the form of their artificial intelligence. The lunar surface, Mars, asteroids, and other celestial bodies are rife with all kinds of robotics and the places they impacted or modified, especially during the early stages of exploration (e.g., *Ranger, Luna, and Beagle 2*). It is a heritage that continues to be part human and part machine.

Key Issues/Current Debates

Space Archaeology also concerns itself with orbital debris. For archaeological purposes, orbital debris has been defined by Gorman (2009: 382) as "any human manufactured object in orbit that does not currently serve a useful purpose and is not anticipated to in the foreseeable future." There are currently huge amounts of orbital debris varying from small flakes of paint to large defunct satellites and all pieces of spacecraft jettisoned, or crashed, continue to exist and are increasing exponentially in space. Low Earth orbit(LEO) and Medium (MEO) and Geosynchronous Orbit (c. 160–37,000 km from the Earth's surface) contain the most debris, while vehicles like the *Pioneer* and *Voyager* spacecrafts are currently the farthest away from Earth in interstellar space. The amount of orbital debris increases yearly as more satellites and exploration vehicles

continue to be launched into space. NASA currently tracks over 34,000 pieces of debris over 10 cm in size, with millions of pieces of debris smaller than 1–10 cm. Referred to in the popular media as "space junk," collisions of debris can cause future spacecraft to fail, be damaged, explode, and create more space junk. The methods to "clean up" or even to evaluate the "junk" are dependent on finding ways to accomplish this and secure international agreements.

Space Archaeology lends itself well to the concept of a cultural landscape, which has become more prevalent in archaeological and cultural resource management studies, but needs to be broadened to include cultural resources off the Earth. UNESCO's World Heritage Convention describes a cultural landscape as the combined works of nature and man (WHC). It focuses on the idea of a site as part of a larger system. For example, the first lunar landing site at Tranquility Base created in 1969, is embedded within a landscape that includes launch Complex 39 at Cape Canaveral, the tracking station in Australia (Honeysuckle Creek), and the myriad facilities that were critical to developing the rocketry (e.g., the Saturn V Test Stand). It can be argued that the Tranquility Base site on the lunar surface is a critical component of the cultural landscape of space exploration. A cultural landscape approach allows for the perception of broad chronological, technological, and geographical patterns in the human interactions with space. Space ceased being a vacuum when humans entered it (Gorman and O'Leary 2007). In effect, it became a place that could be managed and studied in many of the ways that historic places are on Earth. However, in most cases, objects in space or on other celestial bodies present complexities that supersede the disposition of sites on Earth (O'Leary 2009a: 774).

In order to protect heritage in space, approaches must navigate a complex, intertwined area of national and international laws, regulations, treaties, and policies. The archaeological assemblage from the Space Age is from a period that is relatively young and has not been usually considered worthy of preservation. Also, the exploration and use of space is still a functioning, ongoing, and increasingly complex system. Critical components in space have been, for the most part, inaccessible to the public. The field of Space Archaeology and Heritage requires ways to address interpretation, evaluation, and preservation of this legacy. If it is indeed humanity's heritage – one giant leap for humankind – its protection needs to be ultimately international or universal in scope. The World Heritage Convention (WHC) does provide criteria for places on Earth that have "outstanding universal value" under which many space sites and objects would qualify, but they are not on Earth World Heritage Convention (1998). Outer space has not been addressed by the WHC. Because the control and management of space heritage lies in a contested legal arena without specific guidance or laws on cultural preservation written into international conventions, agreements, and treaties, most efforts so far have been within nations (especially the USA). The National Historic Preservation Act (NHPA) in the USA of 1966 came 3 years before the height of the Space Race between the USA and USSR that brought the first humans to the Moon. Historic preservation efforts to date that address space follow USA federal and state laws and the United Nations Outer Space Treaty of 1967 (OST). The Outer Space Treaty asserts that nations which place objects in space or on the surface of celestial bodies such as the Moon are not subject to national appropriation by claims of sovereignty. Essentially, no one nation can own space or, for example, the Moon. But as governed by the Treaty's Article VII, the objects launched into space or on another celestial body are and remain under the jurisdiction of those who put them there (OST; O'Leary 2009a: 774). The Outer Space Treaty also states that space activities should forward humankind's use of space for peaceful and scientific purposes, which could include historic preservation. NHPA, the Outer Space Treaty, and WHC do not explicitly cover the preservation of historic sites and artifacts in space. These cultural resources are not on the Earth; they are a recent past property for which archaeologists do not have a large body of expertise and are at a scale different from which most archaeologists work. The

resources in space and on other celestial bodies are not within any nation's territorial boundaries. Initial and ongoing costs are factors in any preservation strategy and alternatives for space may be expensive, but these costs and preservation strategies can become part of future mission planning. For the Moon as an ad hoc solution, Stooke (2008) suggests that all early lunar sites (CE 1959–1976) be considered significant and protected from any human impacts in the future. Capelotti (2009: 433) has advocated for lunar parks founded on the same principles that currently guide the protection of sites in extreme environments like Antarctica.

The earliest effort to consider preservation issues of space began with the Lunar Legacy Project in 1999 (Lunar Legacy Project n.d.). It is one of the first instances of funded space archaeological research. The New Mexico Space Grant Consortium (NASA) at New Mexico State University, USA, granted monies to B.L. O'Leary and students to focus on the archaeological assemblage at one site, the first lunar landing site created by the Apollo 11 astronauts at Tranquility Base on July 20, 1969. The site was chosen because it is the most iconic of humanity's visits to another celestial body. Also, it was the best test case for the application of US federal preservation law, and one avenue was proposing that Tranquility Base be nominated as a National Historic Landmark (NHL) (O'Leary 2009a: 775). It is the first time archaeologists looked at a site on the Moon as a historic property and evaluated how it could be preserved for the future. These early efforts presented challenges to NASA, who as a federal agency was responsible for complying with the NHPA, and the USA's Keeper of the National Register of Historic Places, who determines the eligibility of significant cultural properties. There was no doubt that the site was significant but the responses in 2000 of these two entities centered on the perception that the Moon could not have NHLs because it would be perceived as a claim of sovereignty and the USA Keeper did not have sufficient jurisdiction or authority (O'Leary 2009a).

Protection efforts for the objects and structures on the lunar surface at Tranquility Base – not the surface itself – began in three different arenas. The first was involving states within the USA to list these resources on their own registers of significant cultural resources. The objects and structures at Tranquility Base were placed on both the California and New Mexico State Registers of Cultural Properties in 2010 (Westwood et al. 2010; O'Leary et al. 2010).California and New Mexico and later Hawaii recognized the artifacts (Westwood et al. 2017). Although largely symbolic, these acts acknowledged that these states had historic associations with the creation of those artifacts and the successful first lunar landing and fit protections under state law. Other states are considering similar actions. An earlier draft bill was drafted for the US Congress to declare the Tranquility Base artifacts an NHL but was not considered. In 2019 Senate bill, S.1694 includes requirements relating to the preservation and protection of the Apollo 11 landing site for licenses to conduct activities in outer space and has been introduced to be considered by committee for debate.

The second arena is at the international level. A resolution by the World Archaeological Congress in 2003 recognized the material culture and places associated with space exploration, and an international Space Heritage Task Force was created that continues to investigate ways of identifying and assessing significance at local, national, and international levels of the cultural material in space whose preservation would benefit humankind (O'Leary 2009a: 777). The International Committee on Monuments and Sites (ICOMOS), an advisory body to the World Heritage Convention for placing sites on the World Heritage List, has become involved in space heritage by initiating a scientific committee. A legal effort for international protection of space heritage is also being currently (2019) undertaken by a nonprofit organization For All Moonkind.

Also finally, NASA itself has acknowledged the problem of preserving space heritage on the Moon and has become involved in the protection solutions. "NASA's Recommendations to Space-Faring Entities: How to Protect and Preserve the Historic and Scientific Value of U.S. Government Lunar Artifacts" (NASA 2011) recognizes that

there are increased technical abilities of space-faring groups including other nations and commercial entities who will go back to the Moon in the near future and provides guidance on visitation to protect both the historic and scientific values at those lunar sites. Interim guidance is provided on lunar design, mission planning, and sanctioning actions which would mitigate damage to significant lunar cultural resources until such time as a more multilateral approach is developed which includes other nations (NASA 2011, 2018).

One of the most exciting areas of research that assists in space archaeology conducted by NASA is the Lunar Reconnaissance Orbiter (LRO) which is in use, in part, to map the surface of the Moon. Although not designed for such use, its digital imaging capacities provide archaeologists with the best remote sensing of the sites created by the Apollo Program on the Moon from 1969 to 1972 (Fig. 3). The scope and ability of this tool is critical to accurately locate and look at the condition of all early lunar sites and document and evaluate the objects, foot and rover trails, and structures on the Moon and plan for their management in the future.

Future Directions

Space and the environment on the lunar surface especially are relatively benign when it comes to preservation. No erosive forces such as wind, water, and organic processes exist on the lunar surface as on Earth. With the exception of the effects of temperature changes and micrometeorite bombardment on the artifacts, they are largely unchanged. The foot trails and rover tracks from over 40 years ago are clearly demarcated. The tools that were developed to explore the universe may be used to greatly enhance the preservation of humanity's first steps off Earth and into the universe. The need for an international legal

Space Heritage Protection, Fig. 3 LRO Image of Apollo 12 site on the lunar surface (August 2011). (Courtesy of NASA)

framework to protect all of humanity's significant archaeological sites and objects on the Moon and in space is critical at this time. With the fiftieth anniversary of the Apollo 11 landing, the commercial development of space, and the participation of many nations in space exploration, the mandate to seek agreements for protection of the material culture of space is clear.

Space, Place, and Architecture in Historical Archaeology

C. Broughton Anderson
Art and Art History, Berea College, Berea, KY, USA

Introduction and Definitions

Space, place, and architecture have a rich and varied history within historical archaeology.

Because Historical Archaeology span over 500 years, much of the data used combine not only artifacts and features but documents and buildings/the built environment as well as folklore, myth, oral history, and ethnography. The influence of Western, capitalist, and colonialist processes remains a dominant undercurrent, and while much research of the past has been filtered through this Western perspective, a renaissance in indigenous archaeologies and the insertion of indigenous perspectives stands to challenge our scientifically grounded constructions of space and place, and with good reason. While many historical archaeologists have been conscious of indigenous epistemologies, it is only within the past 20 years that both indigenous archaeologists and archaeologies have established themselves and their approach in their own right.

Archaeological research attempts to understand relationships between people and things and those relationships are created, maintained, and resisted within a spatial context. Archaeologists categorize and label space when formulating where research will take place (our sites) and during excavation with test pits and trenches. Our choices quantify our limits of enquiry. We determine how space was used based on the materials we pull out of the ground and from our experience in the field. At the same time, we are attempting to understand these areas in a social and cultural context and thusly creating places of meaning. Tuan writes: "Space and place are basic components of the lived world; we take them for granted. When we think about them, however, they may assume unexpected meanings and raise questions we have not thought to ask" (1977: 3). These unexpected meanings and unknown questions are what drives us.

Space has often been defined in terms of a container or vessel which bounds human action. It is detached and without meaning; it is to be mapped and measured; it is an object and has physicality. Lefebrve (1974) in the seminal *The Production of Space* offered three axes of understanding of space in what he defined as the perceived or spatial practice of every day life; the conceived or representations of space created by cartographers and planners; and the lived or representational space which is derived from the imagination. David Harvey chose to take space further, removing the absoluteness of it, and instead looking to relationships. Harvey expanded on this triad through his "grid" of spatial practices. Here, Harvey creates conditions that when used in relation to particular social relations, space can be more clearly understood: "Under the social relations of capitalism, for example, the spatial practices portrayed in the grid become imbued with class meanings. To put it this way is not, however, to argue that spatial practices are derivative of capitalism. They take on their meanings under specific social relations of class, gender, community, ethnicity, or race and get 'used up' or 'worked over' in the course of social action" (1989: 223).

Historical archaeologists have developed approaches which address the ideas of place and space. The aim of this entry is not to compare or contrast these approaches, but instead, flesh out

the data upon which historical archaeologists base their claims. This entry considers the landscape as the container, if you will, of the physical, social, and cognitive data gleaned from relationships between people and their material world. Because landscape, in its broadest definition, is where human action is carried out, a large portion of this entry is devoted to landscape as a space upon which archaeologists carry out their work.

Space and Place on the Landscape

Parts of the sections on Space and Place on the Landscape, Landscape and Power, Texts as Spatial Practices, and Social mory represent material from my unpublished dissertation [Anderson, Christine Broughton Anderson "Uncovering and Recovering Cleared Galloway: The Lowland Clearances and Improvement in Scotland." PhD diss., University of Massachusetts Amherst, 2015]. Building off the early use of settlements within New Archaeology, some theoretical approaches have sought to bridge the gap between space, the culturally bare, quantifiable, backdrop to and product of human action always in process, and place, the more static, fixed emotive "location of past actions, experiences, and memories. . ." that define an individual or group of people (Smith 2008: 16). The works of Hoskins (1954) for example, laid the groundwork for a critical assessment of landscape, but his approach did not fully engage the concept that landscape is a cause for and effect of human behavior or the "medium for and outcome of action and previous histories of action" (Tilley 1994: 23).

Landscapes are complex with infinite meanings constructed around individual and collective experiences and situated in a physical context – space and/or place. This "materiality of social relations" for Bender means landscape is dynamic – just as social relations are in constant process so too are landscapes (2002: 104). Landscape can be conceptualized in a multitude of ways including as an idea that frames how space is constructed and reconstructed and as what Cosgrove describes as "a blend of land and life," that which gives an area meaning (2006: 50). Overarching these perceptions is the notion that landscape is relational to the illustrative – how its aesthetic value marks and demarcates space in social, economic, and political terms. In essence, the process by which landscapes are altered to broadcast or hide information, experiences, and relationships is wrapped up in the visual nature of them.

Time is a crucial element of the visual: "Landscape is time materializing" (Bender 2002: 103). The urge as an archaeologist is to freeze time to locate one landscape (it, too, being frozen with definitive cultural material that informs us of social phenomena). However, it is almost impossible to situate one landscape in a moment with one outcome; "the" landscape becomes "many" landscapes as they are perceived, experienced, and imagined on a variety of scales, including at any given time. "Nested landscapes" is another way of looking at the diversity of people and their experiences (Ashemore and Knapp 1999). As such, the idea of multiple landscapes becomes more concrete: "people create their sense of identity through engaging and re-engaging, appropriating and contesting the sedimented pasts that make up the landscape" (Bender 1998: 25).

Landscape and Power

The perception of landscape within a capitalist system hides its multivocality because of the ways in which it has been constructed around specific needs. As the integral component of the means of production, land as private property becomes the space of power/domination/resistance. In other words, it is the central locus of changing attitudes because "power is manifest in social relations where there is asymmetry in the ability to command material resources" (Driscoll 1988: 169). Physically, power is exercised in the disciplining of space: the building of walls, for example, demonstrates power to alter movement across the landscape.

Cognitively, the interrupting of the "social fabric" around which the population had constructed their lives is carried out by the severing of people's access to public land, the changing of farming practices, the breaking-up of communal living arrangements (see Lelong 2000). Counter to this,

resistance too is practiced as physical and cognitive attachments to land are challenged. Land, then, is the space in which power/domination/resistance is played out. Research that explores the ways in which stakeholders have worked within this process is of crucial importance to understanding processes which remove or clear disenfranchised people from the landscape (see Strang 2001; Harrison 2004; Rigney and Hemming 2008; Paterson 2008; Wiynjorroc et al. 2005; May et al. 2005; Given 2004; Nairouz 2008, White 2008; Nicholas 2005).

Clearing is apparent in its design to create an empty landscape, void of humans. What may appear as culturally bare is not. Archaeologically these landscapes are crucial markers of changes in human behavior modified through physical and ideological representations of power. Physical representations of power, from field walls to elaborate architectural structures, indicate shifts in the ways space was reorganized, reconstituted, and reassigned for specific purposes. Ideological changes accompany physical ones. Processes of "ideological clearing": the act of writing people off their indigenous lands to create an empty and available landscape flesh out the ongoing process of erasing ethnically, racially, or economically diverse groups from both physical and mental landscapes. Clearing encompasses both past and present processes of erasure of particular groups of people. While the removal of people is evident in what is or is not present on the landscape, the process is rooted in written documentation.

Texts and Spatial Practices

Texts, for historical archaeologists, are contextually significant and include a range of material culture from written documentation to maps to images. In all forms, texts are embedded with social meaning and reflect power as well as resistance. However, with a shift from the text as material culture to the language of the text as producers of material culture, space and place in particular, texts have a dual role.

The dual role of documents in modifying space and behavior follows previous research on spaces of confinement within urban settings during industrialization (see Beaudry et al. 1991; McGuire 1991; Mrozowski 1991; Casella 2001; Garman 2005). Documents maintain a power relationship between people, but more importantly, it is the language of the document, which requires one segment of the population to produce materials designed to modify their space and thus their behavior. In essence, documents require people to produce their own spaces of domination and control. As metaphysical representations of power, documents promote domination or control in two critical ways: the act of recording, thus legitimizing an idea; and cultivating a sense of "power to" transform by offering constructive guidelines concerning behavior while also covertly disciplining (Anderson 2016; Garman 2005: 7). The ways in which these discourses are translated onto the landscape demarcate a dynamic and dramatic shift in both the perception and use of land within colonial and capital ventures. Engagements with discourses of power result in "spatial overwriting" a practice of indelibly linking stakeholders to or severing them from landscapes, producing and reproducing them in ways that support or deny dominant perceptions (Rubertone 2008: 15). All texts can assist in the exploitation and domination of specific groups of people by writing them out of the story or off the land. Though one focus of historical archaeology is to seek out the "voiceless" population, that population often remains difficult to find (Moreland 2001: 105). By changing focus from simply finding these populations to critically analyzing strategies or tactics that can be or have been used to erase them, disenfranchised groups become less elusive. One such strategy of erasing is through the restructuring of social memory and the reformulation of history.

Social Memory: Invisibility and Multiplicity in Place Making

Embedded within group dynamics are the roots of hegemony. The power to construct specific places through commemorations, celebrations, and performances is held by those who dominate, and it constructs the conditions that help enable domination. Halbwachs reflects upon this when he writes, "...the mind reconstructs its memories under the pressures of society" (1992: 51). He concludes this line of thought by stating society

also requires of its members a touching up of memories, altering them in some fashion so that "we give them a prestige that reality did not possess" (51).

It is a critical point that memories become an agent of materiality. In Lowenthal's chapters on memory, history, and relics, he writes that these three "...offer routes to the past best traversed in combination" (1985: 249). While Connerton (1989) and Halbwachs (1992) offer insight into how memory is constructed, transmitted, and maintained, Lowenthal explores how the combination of history, memory, and relics can produce a more "credible" story. Memory, history, and relics act as "mutual metaphors" where memories are simply traces of things recalled; artifacts and "things," however, are products of and precedent for culture (Wobst 2001). It is the artifact, space, place that brings history to life, retranslates it into memory and changes its power and influence.

Lowenthal goes deeper by suggesting that we consciously alter history and/or artifacts – most often improving it – to produce a desired result or interpretation (1985: 326). And, in doing so, we convince ourselves, through fabricated memories that events happened much differently than perhaps they actually did. The importance in constructing a history that tells a desired story and a place for that history to exist far outweighs the marginalization of people to whom the events are intimately linked.

More importantly, the acts to "improve" history are not limited to individuals but are conscious and deliberate practices of states, especially in transitional periods of identity. Making traditions, assigning holidays, and enacting commemorative performances in which a nation finds cause to remember are intricately linked to how we, as members of a state, perceive our history and our identity towards and with others. This hegemonic rewriting of history privileges the bourgeois "story" by making it plausible and thus erasing the lower classes or making them less visible in spaces that are important. All subsequent material constructions in relation to filling the void produce an emotive, ideological experience for the dominant groups. However, and following Lowenthal's argument, if these processes do not fully succeed in maintaining a particular trajectory, reinvention, or fabrication of particular stories assist in achieving the desired outcomes.

The mobilization of specific histories, traditions, and cultures to legitimate a meta-narrative about nations support the compartmentalizing of national history (Finlay 2001: 386). Identity and the use of history and other aspects like language and culture is not about establishing a space for "being" but a guideline for "becoming" a particular place in the future (Hall and du Gay 1996: 151). The politics of history and place-making have prioritized certain areas and their histories and excluded others, namely, those that are at the periphery. Though these peripheries are situated within territorial boundaries that make up a nation, their contextual "place" within the nation is complex as they struggle to cope with often having little "historical or mythical capital" (Popular Memory Group 1982: 209).

Oral history – with its unique mix of memory, myth, and "fact" – can challenge the validity of the written record and increase the dimensionality of research. Archaeologists engaged with oral history find a dynamic link to knowledge not recognized in other sources. In the United Kingdom and Ireland, for example, Rotman (cf2008) has employed oral history on both sides of the Atlantic to explore the role of place in the Irish Diaspora. Bender (1998) and others have all included myth, folklore, poetry and song, heritage interpretation, and/or oral history as means of exploring the vast array of alternatives that are informing locals about their world. Ethnography also offers a dimension to archaeological research that includes both the interpretation of the past in the present. For example, in Bender's (1992) efforts to move beyond the static-ness of place in time in her work with Stonehenge, she includes conversations or ethnographic moments to explore how no one story or bit of information is necessarily more authentic or right than another. Employing oral history opens the door for what the Popular Memory Group elaborates as becoming archaeologists of the present as well as of the past (PMG 1982).

Contemporary historical sites, whether manufactured heritage attractions, specific

architectural examples, or ruins, offer a glimpse into social, economic, and political constructions thus providing a richly contextualized site of study. The exploration into local experiences with memory and materiality at contemporary sites help tease out how these encounters reflect underlying tensions generated from a nation coming out of colonial relationships. Materiality and memory are embedded in the processes of everyday life as well as the more broadly reaching construction of place within the developing national identities. The "excavation" of contemporary sites as an alternative to understanding past constructions of history and its role in identity and place making is critical. Contemporary sites are artifacts. They are material dimensions produced through and by social relations and are part and parcel of wider, more encompassing landscapes imbued with power.

Because there is a constant "network of power" engaged with context and the landscape, contestation is ever present. Functioning at the local level, landscape is the terrain on which political, economic, social, and cultural forces play out and it is here where we see how, as Maryon MacDonald states, "Identity is forged out of the structures of the present, and turns to the past for self-derivation" (1989: 97). Social interaction with and between local inhabitants, their interests, and intentions as members of a place are indicative of such forces as boundaries designed to include and exclude are constructed through social interaction. As agents in their locale, individuals and groups practice strategic processes, which are representative of their position in hegemonic and counter-hegemonic dynamics. The product of such practices thus becomes symbolic of past and present process.

Global Directions for the Future

The above outlines the physical, social, and cognitive spaces at play in historical archaeology. Analyzing texts, constructing and reconstructing history and/or heritage, and working with memory are central to our understanding of past and present on a global scale. To return to Harvey at this juncture is prudent. His ideas on "spatial consciousness" or "geographical imagination" clarify our engagement with texts, histories, heritages, and commemorations. To quote Harvey at length:

> This imagination enables the individual to recognize the role of space and place in his own biography, to relate to the spaces he sees around him, and to recognize how transactions between individuals and between organizations are affected by the space that separates them. It allows him to recognize the relationship which exists between him and his neighbourhood, his territory, or, to use the language of the street gangs, his "turf". It allows him to judge the relevance of events in other places (on other peoples' "turf")—to judge whether the march of communism in Vietnam, Thailand, and Laos is or is not relevant to him wherever he is now. It allows him also to fashion and use space creatively and to appreciate the meaning of the spatial forms created by others (1973: 24).

Further, Harvey's "grid of spatial practices" gives depth and analytical structure to our relationships with space and place, especially in terms of capitalism (and for that matter colonialism). Within the framework are refinements, axes by which work within historical archaeology can better flesh out the immense social networking of groups functioning within the culture of capitalism. These conditions – *Accessibility and Distanciation, Appropriation and Use of Space, Domination and Control of Space, Production of Space* – add nuance to our interpretations of the material world. In combination with the ever-growing technologies of spatial analysis, historical archaeologists have, more than ever, powerful tools with which to query the past and present (1989: 219–222).

With the integration of distinct spatial analysis technology from ground penetrating radar to LiDAR data, spatial analysis has developed into its own subdiscipline within historical archaeology and deepens research. With the application of such data, the level of analysis and synthesizing of larger spaces (for comparative purposes) allows for a greater understanding of the use of space within early historical settings. Within indigenous communities, such tools also can support land right claims, for example, and can locate sites of potential occupation as well as combat standard

colonial spatial barriers like architectural structures, walls, foundations, and the like. However, none of these tools can be used in isolation.

Work in Scotland and Ireland demonstrates the breadth of research in which space and place are a focus. For example, Dalglish's (2003) work centered on home lot and interior domestic spaces and the routine of daily life on the Mull of Kintyre during Improvement. This work illuminates the strategies of adapting to and resisting Improvement within spaces in the southern Highlands. Michael Givens' (2004) work on Highland resistance landscapes focuses on the illicit making of whisky as a means of recreating the communities that had been disrupted by clearing. Bangor-Jones (2000), Basu (2000), Lelong (2000), and Symonds (2000) demonstrate innovative archaeological methodologies as a means to better contextualize understudied populations, drawing on documentary sources, social memory, and settlement patterning variation. Gazin-Schwartz's (2008) work focuses on visualizing the "empty" landscape on Raasay, in the western islands of Scotland, and the problems faced by archaeologists who attempt to work in these cleared spaces. In parallel, Angele Smith's work on Irish maps as critical interpretative tools for visualizing the "colonizing" of the region is integral when such maps tend to make the lower classes invisible and where scant documentary evidence is available on them (Smith 2001, 2008). Two larger-scaled projects conducted by RCAHMS (Royal Commission on Ancient and Historic Monuments Scotland) involved a range of methods, including historic land characterization schemes as well as oral histories and textual analysis. *But the Walls Remain* and *Well Watered and Sheltered* set the standard for such projects.

Historical archaeologists are in a powerful position to continue to challenge the direction in which archaeology, in general, heads. Research from schemes such as IPinCH (Intellectual Property Issues in Cultural Heritage), for example, out of Simon Fraser University and continued work in Australia and New Zealand with Aboriginal and Maori descendant populations, trajectories which involve all stakeholders must be continued. In terms of space, place, and the built environment of which landscape is a part, work with indigenous groups will deepen our personal "geographical imagination" as well as aid us in our work to inform a global audience.

Spain and North Africa: Islamic Archaeology

Alberto García Porras
Department of Medieval History, Universidad de Granada, Granada, Spain

Introduction and Definition

Interest in the Western Islamic world, essentially the Iberian Peninsula and North Africa, is long-standing. The presence of well-preserved buildings and monuments and numerous works of art has generated a particular approach since the mid-nineteenth century, sometimes close to exoticism. Appreciation of the arts and antiquities of these societies, whether wiped out and existing only in memory as is the case with Spain, or still present as with North Africa, contributed to the considerable increase and development of studies on Islamic history in these regions. Without doubt, in the case of North Africa, the fact that the area had fallen under the control of Western political powers, mainly France and Spain, helped the development of research, although frequently with a focus on local custom.

However, archaeology was involved only slightly in this process of historical reconstruction until well into the twentieth century. Indeed, at least regarding Spain, it was not until the 1970s that archaeological studies would bring new ways of developing knowledge of these Islamic societies.

Despite this, the excellent advances and the indispensable works that appeared from disciplines such as history of art and history of architecture by authors such as Georges Marçais (1954), Henri Terrasse (1932), Manuel Gómez-Moreno (1951), or Leopoldo Torres Balbás (1949) in the first half of the century should not be forgotten. These authors, the most outstanding among a considerable group, established the fundamentals of the study of the art, archaeology, and architecture of Western Islam. These authors' perspectives cannot be considered strictly archaeological, for it is still firmly rooted in art history and, as such, chiefly focused on architecture and urbanism. Somewhat later, authors such as K. A. C. Creswell (1959) presented a renovated positivist perspective. K. A. C. Creswell focused most of his work on the Eastern Islamic world, although he also did some research in the Alcazaba of Balaguer (Lérida); in palaces such as the Aljafería, in Zaragoza, and Medina Azahara; and in mosques such as Córdoba and Toledo, as well as in the Maghreb, specifically in Marrakech, Kairouan, and Tinmal, and O. Grabar (1973), who centered his research in Spanish monuments such as the Alhambra (Grabar 1980).

From the 1970s, the situation changed considerably. Theoretical and methodological progress in the discipline of archaeology throughout the 1960s, particularly regarding the chronological sphere of prehistory, had allowed for the development of the discipline in the Mediterranean area, albeit with a certain delay. The archaeology of the Islamic world was no exception. In the case of Spain and North Africa, many researchers – mostly coming from the fields of medieval history or prehistory – became involved in applying archaeological and anthropological methodology with a view to enriching knowledge of medieval Islamic society. This was an important catalyst for advancement in historical and archaeological research carried out in al-Andalus. It led to the birth of a new discipline, medieval archaeology, hitherto scarcely explored, which was to develop into pioneering and innovative work on al-Andalus, and a vehicle by which to introduce new streams of research.

For North Africa, the influence of countries external to the region was essential. The pioneer in this respect was without doubt the French school, notably improved since the end of the 1960s, which continued to act as an engine for research with the participation of some local collaborators. The first projects that were put into action were directed at increasing knowledge of ancient times and failed to properly appreciate medieval Islamic levels. It was not until the end of the 1970s and beginning of the 1980s that work specifically addressing the medieval era began. These first studies, applying the so-called extensive archaeology, concentrated on the analysis of territory by means of broad archaeological surveys in northern Morocco. Other teams of diverse origin rapidly became involved, including Americans (Sijilmasa, Basra, Djerba, Qsar el Segir), British (Volubilis), Italians (Rif), French (Rif), and Spanish (Sus-Tekna), and successfully formed mixed teams. The work carried out in the context of these projects has served as a catalyst for the development of Maghrebian research in recent decades. Some of the projects are still active today (Sabra al-Mansuriya) providing information of great interest. In spite of this, research in North Africa shows a certain delay in comparison to developments in the Iberian Peninsula.

From this time onward, those involved in this research began to intervene as of right in the process of the historical reconstruction of Western Islamic societies and not only in the limited fields of art and architecture (Sénac 2007, 2012). With a new technical language, at times no doubt incomprehensible to their historian colleagues, they rejuvenated the academic field. Their work began to open new debates of great importance that today continue to arouse scientific discussion, spur the development of the discipline, and increase our knowledge of medieval Islamic history in this region. We will refer to some of these debates in the following section as they serve to highlight the state of current knowledge.

Historical Background

From the Ancient World to Western Islam

At the turn of the seventh to eighth century, the Iberian Peninsula and North Africa were conquered by Muslims. Until then, the evolution of these territories had been similar, although with some distinctions, to that of the rest of the territories that had been integrated into the Roman Empire. In late antiquity the area underwent considerable upheaval due to barbarian invasions (mostly Visigoths and Vandals, with lesser incursions by Suebis and Alans), and a whole series of transformations of the structures of organization belonging to the Roman era took place. These, however, had already begun to be modified before the fall of the last Western emperor. If any single thing characterizes this field of study, it is the presence and influence, in varying degrees, of the Byzantine Empire which saw itself as affected by the Iberian Peninsula and North Africa, lands that would later be controlled by Muslims.

Regarding the Iberian Peninsula, work on this period has centered on various fundamental aspects (Gutiérrez 2012; Macias 2012). First is the study of cemeteries, with particular interest in the analysis of their organization, location, and funerary practices based on the associated material culture, with a view to clarifying the identity of the buried. Second is a focus on Visigothic architecture, especially that used in known churches, and the transformation of rural settlements (the end of the late Roman *villae*, the emergence of new kinds of settlement such as farms and small towns) and in the cities, which underwent a process of significant transformation, especially evident in metropolis as distinct as Mérida, Cartagena, Tolmo de Minateda, or Recópolis, all of which have been subject to rigorous archaeological intervention (Fig. 1). Third is the characterization of rural settlement patterns and their transformation over time throughout the early medieval period, including not only domestic structures but also peasant landscapes and defensive structures, some of which are hard to recognize. Finally, the analysis of material culture, especially pottery, where large technical and morphological changes are observed in the ceramic

Spain and North Africa: Islamic Archaeology, Fig. 1 El Tolmo de Minateda, Hellín, Albacete (Abad Casal et al. 2012: 362)

repertoires that need to be correctly explained. Importantly, all of these aspects have been analyzed as markers for the process of social Islamization that began with the conquest of Hispania by the Berbers.

For North Africa, research has concentrated especially on the second of these themes, the cities and changes that took place in their rural hinterlands. This includes isolated case studies of great interest. A few of these are located in Libya (Leone and Mattingly 2004 and Leone 2007). In Tunisia, most work has traditionally revolved around three early cities, al-Abbasiyya, Raqqada, and Sabra al-Mansuriya (and partially in Mahdiya and Tunis) (Cressier 2012). In 2003, an ambitious, and theoretically novel, project was undertaken in Sabra al-Mansuriya (Cressier and Rammah 2008), and the results have been excellent. Something similar has occurred in Uchi Maius (Gelichi and Milanese 2002). In the central Maghreb, especially Algeria, we must stress the archaeological works carried out in the Qala of the Banu Hammad and in Sedrata (and partially also in Hunayn and Agadir). In Morocco, in contrast, archaeology had little presence in otherwise comprehensive studies about great cities such as Fez, Rabat, and Marrakech, and early attempts to give archaeology a more prominent position, for instance, in Zagora and Nakur, went largely unnoticed. The first cooperative projects began in the 1970s in Qars al-Seguir (American-Moroccan) and Belyounech (French-Moroccan). This trend continued with the projects undertaken in Jbala-Gomara and Basra and continues in our days, in Sus-Tekna (Spanish-Moroccan) (Onrubia 2004), Sijilmasa (American-Moroccan, Messier and Fili 2002), Volubilis (British-Moroccan, Fentress and Limane 2007), and Nakur-Aghmat-Tamdult (Cressier 2007, 2010). We cannot forget the interesting results, at different levels, including ceramic studies, domestic areas, urbanism, military architecture, etc. yielded by the projects undertaken by the Spanish city of Ceuta (Hita and Villada 2012).

The prosperity of these North African cities outlasted the fall of the Roman Empire, although changes are evident as early as the fifth and sixth century (abandonment, transformation of certain public spaces, the building of churches, development of fortified elements). The Arabs established themselves in this network of transformed cities at the time of the conquest, and these settlements lasted into the first centuries of the medieval period, due to their continued occupation by urban elites. In any case, we must not forget that, in contrast with what happened in the Iberian Peninsula, most of the Maghreb had not been Romanized and the indigenous substratum, which was essentially tribal in nature, was clearly predominant, resulting in social processes that had little resemblance with those taking place in Hispania. The involvement of tribal groups in the development of cities was substantial, which explains the early morphology of some of these urban nuclei. Other factors, such as the creation of exchange hubs and the exploitation of certain resources (mineral or agricultural), also played a role in the location of these cities (Cressier 2012).

At any rate these issues were directly linked with lines of investigation that had developed some time previously in the rest of Europe, although each with their own local characteristics. This wider debate analyzed the changes that took place after the fall of the Western Roman Empire and into the beginning of the early Middle Ages (Wickham 2005: 902–945). After the Arab invasion and conquest of these territories, the situation changed substantially. The factual account and the archaeological discourse changed to the same degree.

Islam in the West: Al-Andalus and the Maghreb

Transformations in Patterns of Settlement After the Muslim Conquest

The Arab conquest of North Africa and the Iberian Peninsula is a watershed in terms of approaches to research. Traditional theories, at least in the case of Spain, accepted only with difficulty the incorporation of this area into the Islamic world. For a long time, it was considered that Islam did not result in more than a few superficial cultural or religious changes in this territory, without implying radical developments to the society of the Iberian Peninsula. There were even those who denied that the invasion occurred, considering it more an "orientalization" of society than a

conquest and Islamization of the Peninsula (García Sanjuán 2013).

The work of Pierre Guichard, from the late 1970s, came to deny this view, acting as a starting point for a comprehensive revision of studies on al-Andalus. Influenced by structuralist/functionalist social anthropology, he argued that medieval society in al-Andalus and North Africa presented a social and familial structure belonging to the Islamic world, very different to that which existed in the feudal-Christian area of the Peninsula. This would confirm that the social impact of the Arab-Berber invasion and conquest of Hispania was wide and profound (Guichard 1976, 1990–1991). Initially based on written documentation, he subsequently undertook archaeological research, carried out in collaboration with other French colleagues (Bazzana et al. 1988), to observe and interpret the documented changes to the organization of settlement and material culture of al-Andalus. The work initiated by these researchers served as strong motivation for the creation of a new school of archaeology, dedicated to the study of al-Andalus, which has made new and rich contributions to the process of historical reconstruction (Fig. 2) (Bazzana 1992; Boone 2009).

The analysis of landholding initially occupied the core of these authors' investigations. Originally focused on the study of the various documented settlements in al-Andalus, research soon began to center on the relationships that existed between them, especially between the fortified settlements; the castles (*hisn*/*husun*), very common in Andalusian geography; and the rural settlements under their influence, the farmhouses, as well as those linking rural settlements and the flourishing early Andalusi cities. A common perspective was that this organization reflected the society established in the Peninsula after the Islamic conquest. The fortifications were central to the organization of rural territories in al-Andalus, but instead of showing a morphology and structure similar to the older (feudal) fortifications, analysis of the settlements showed that they were to a greater extent a reflection of a segmented society, tribally organized, and at the same time an expression of the fiscal implementation of the state in rural territory. Settlement organization was thus a reflection of the delicate balance existing between the Islamic state, the most representative spaces of which are to be found in urban contexts and the rural communities

Spain and North Africa: Islamic Archaeology, Fig. 2 Tirieza Castle, Murcia (Eiroa Rodríguez et al. 2009)

that organized the cultivation of the land and defended it in case of danger.

The model suggested by these French authors was contested at the time, as much for the chronology of its proposed implementations as for the functions it attributed to a fortified space. Despite including a varied typology of fortified settlements, it seems clear that the model suffered from a certain inflexibility and stagnation, so that as studies developed, some of its aspects underwent revision and development.

Rural territories have been documented where the presence of fortified settlements is minor or practically nonexistent. However, in some regions, it has been possible to sequence the development of fortifications through the Middle Ages, from an initial stage in which diversity indicates a process of social transition between the Visigothic period and a fully Islamized one. Here, the introduction of Arab-Berber population groups played a fundamental role alongside the integration of the diverse communities present in the initial Andalusian phases, moving toward Islamization not only in religious terms but also as regards linguistic, cultural, and social practices (Acién 1989).

Authors such as M. Acién (1995), E. Manzano (2006), or S. Gutiérrez (1996) have emphasized this process, including the changes that can be observed in the material culture of this period as well as the fortified settlements and rural centers, in their discourse. These changes refer especially to the practices and centers of production of ceramics and their networks of distribution, as well as to the importance and influence of urban centers, all of which reflect the degree of continuity or disruption between the late Roman and Muslim worlds.

This process of Islamization, which was not without conflict and resistance, started from an advanced stage of destructuralization within the Roman world, which is generally confirmed in various ways: in the transformation of late Roman settlement patterns, with documentation of a clear tendency to occupy high ground and occasionally "marginal" zones, in new forms of cultivation in productive areas, and in the transformation of the urban network, with decline, abandonment, and new foundations. All this was accompanied by profound changes to artisanal productive structures and in networks for the exchange of products. These are most clearly demonstrated by changes to the ceramic corpus, with the appearance of nonstandardized repertoires made using basic techniques and with relatively localized distribution. This transitional process continued until the end of the tenth century, when it is generally agreed that the process of Islamization of al-Andalus society was largely complete (Gutiérrez 2012).

The culmination of the process coincides, according to this view, with the establishment of the Umayyad Caliphate of Córdoba and is visible in the consolidation of the settlement model discussed above, as well as in changes to material culture, especially in the ceramic record. From this moment wheel-made vessels and glazed dishes appear more frequently.

Clearly this interpretive model, incorporating new factors and variables, brings greater complexity to the general discourse, while the localized studies that developed during the 1990s in Andalusian geographic zones particularly have shown that the rhythms and profiles of the process vary from one area to another, presenting specific regional characteristics.

This model of land use underwent important transformations over time. During the Almohad era, a process emphasizing the construction of fortresses apparently played out, especially in the east (Azuar 1988, 2016), although this phenomenon could equally apply to the rest of al-Andalus. Other changes related to occupation and in places cultivation of the land. For the final stage, the Nasrid period saw fortified nucleation of notable complexity, with the appearance of new materials and elements in these structures indicating the penetration by urban influences of these areas (Malpica 1996, 2008), along with the more obvious presence of Nasrid power (Acién 1999) (Fig. 3).

Regarding North Africa, research has not allowed similar conclusions to be drawn. The rural settlements, still incompletely studied, do not evidence similar organization. Although the Arab invasion and conquest initiated a process of

Spain and North Africa: Islamic Archaeology, Fig. 3 Moclín castle (Granada)

profound social and cultural transformation, the result in terms of settlement is not comparable. Fortifications, while still numerous in this territory, do not assume the same importance; they apparently reached in al-Andalus. However, the occupation of space by small nucleated settlements dedicated to the cultivation of their hinterland and based largely on the use of irrigation techniques does seem to extend through North Africa, although the scales vary at a regional level.

It should be noted that this interpretative change can be attributed as much to developments in archaeological methodology as to the fields of inquiry themselves. If at first, research was fundamentally based on territorial analyses, beginning with extensive landscape surveys from the middle of the 1980s, the development of techniques of spatial analysis, the emergence of urban archaeology, and the development of ceramic analysis have permitted the incorporation of new elements into the discourse. These elements have favored the development of new theories and a surge in new fields of study. We will focus on these below.

Key Issues/Current Debates

Settlement and Resource Exploitation: Hydraulic Archaeology

The explanatory model outlined above was initially directed to a great extent toward rural settlement, without actually excluding cities. It was because of this that some researchers naturally departed from the model and began to highlight the close link between fortifications and the exploitation of resources, in particular cultivated fields and irrigated agriculture (Cressier 1991).

The configuration of Andalusian territory in terms of these parameters from the tenth and eleventh centuries meant the construction of a new rural landscape featuring smaller units of population in the form of small nucleated towns called *alquerías* (from the Arabic *al-qarya*) and their associated hinterlands. The analysis of these small towns, little known due to their long occupation and difficulties of archaeological analysis, has contributed some knowledge of these productive spaces.

In this way the field of hydraulic archaeology has emerged and broadly developed within

Andalusian studies. The works of T. F. Glick (1970) and, above all, of M. Barceló (Barceló et al. 1988, 1997) and H. Kirchner (Kirchner and Navarro 1993), developed primarily in the eastern area of the Peninsula and in the Balearic Islands, have laid the foundations of this new discipline.

Following the proposals of P. Guichard, these researchers have linked the design, construction, and management of these irrigated spaces to the farming communities, generally organized in clans. From this perspective, the existence of these spaces, rather than solely being determined by geographical character or similar variables, is considered to be a social choice, and the criteria that govern them have been developed and should thus be explained by rural communities' own characteristics. The design of these spaces indicates a considerable organizational effort on the part of these communities, and their management cannot be understood unless from cooperation and collective effort within the community. The development and evolution of irrigated land thus denote strategies and formulas for growth in these groups.

The creation of these agricultural systems (Malpica 2012–2013) marked a considerable modification of Andalusian rural ways of life, although on a local scale. This involved the application of catchment, distribution, and complex storage techniques, on occasion originating from the east. At the same time came the introduction and acclimatization of new crops, previously unknown in the Iberian Peninsula or North Africa, the products of which were not suitable for prolonged storage. This can only be explained in light of an economic context facilitating their dispersal.

Without casting doubt upon the importance of these agricultural areas in medieval al-Andalus and the Maghreb, in recent times, new paths of investigation are being explored that incorporate problems associated with nonirrigated land and livestock in the rural Andalusian lifestyle. These issues are currently little known.

The "Alquerías" and Modes of Habitation

These rural groups, which were characterized by high homogeneity and social cohesion as well as administrative autonomy, were established in the alquerías. The settlements' morphology, as far as we know, reflected the characteristics of its community of rural landowners or workers. They appear to be very distinct from settlement forms occurring in the rest of the European continent (Guichard 1988). The alquerías are perhaps one of the least archaeologically known aspects of the rural Andalusian world. Very few have been carefully investigated archaeologically (Jolopos, Castillo del Río, Torre Bufilla, El Castillejo, Ponta do Castelo – Carrapateira – etc.) and those that have shown diverse characteristics (open or walled fields, concentrated or dispersed, etc.), although they present a similar urban organization, comprising various cores connected by intricate lines of communication, which do not follow an orthogonal organization, and where large public spaces are virtually absent (Fig. 4). All of them seem to have a similar relationship with productive areas, be them irrigated or dryland agricultural fields, grazing meadows, or wooded areas.

The inhabitants of these small nucleated villages managed a vaguely delimited territory in which were located areas exploited for agriculture or livestock or as woodlands. These spaces or lands were framed by statutes and particular legal recognitions (Lagardère 1993; Trillo 2004).

The dwellings that made up these small towns, despite the existence of variation in dimensions and typological form, reflect a single model from the tenth century onward. In recent times, the emergence and transformation of this process, as well as its social implications, have been analyzed in detail (Gutiérrez 2013). This model is based on the existence of a central courtyard around which were rooms in an L- or U-shape (Bazzana 1992). The presence of a hall, a space reserved at the heart of the home for the intimate activities of the familial sphere, appears to be a specific feature. The rooms, while still presenting a marked multifunctional character, emphatically separate areas of private repose from those designated as the kitchen or as rooms for daily life. The profiles of these dwellings, where they have been analyzed in detail and in light of data concerning the domestic assemblage, are those of an extended family where characteristics of relatedness were clearly present (García Porras 2001). The materials used for their construction were

Spain and North Africa: Islamic Archaeology, Fig. 4 El Castillejo, Los Guájares, Granada

varied, although walls of rammed earth appear most frequently. In any case, their construction made use of materials found close to the settlements and did not require any complex techniques so that it could be undertaken within the community.

The Urban Sphere

The city is one of the most extensively studied aspects of Andalusian archaeology in recent years and could even be considered to be one of the most dynamic, as the flow of new data coming from archaeological interventions has been continuous; syntheses of the subject, however, have been more scarce. In any case, research has managed to move beyond the milestone that was in its day marked by the work of L. Torres Balbás (1970), who emphasized the topographical characteristics that were present: the planning of roads, the forms of water supply, the presence of certain characteristic elements, etc.

The majority of authors that have dealt with this subject have agreed that there was a lack of continuity between the ancient or late Roman and the Andalusian cities, even where topographical or occupational levels of both periods exist. At this time, changes to the urban network were substantial, erasing any functional heritage and changing its characteristics in a fundamental way that barely conserved the memory of what had gone before.

One of the preoccupations of recent times has been the origin of these cities (Cressier and García 1998). There is no doubt that the Arab-Berber invasion and conquest resulted from the occupation of existing urban centers in the Peninsula, whether or not they were already immersed in a process of marked decline. The formation of the first cities in al-Andalus during the amiral period was a result of the transformation of certain existing centers, as happened in the case of Toledo; the Visigothic capital itself, Sevilla; Córdoba; Mérida; Valencia; or Zaragoza, among others, and of foundations connected to the new power that emerged in a spontaneous way from preexisting rural settlements. Foundations linked to the process of conquest do not seem to be documented on the Peninsula, as were Kufa and Basra in Iraq, Fustat-Misr in Egypt, or Qayrawan in Ifriqiya (Fig. 5).

Spain and North Africa: Islamic Archaeology, Fig. 5 Suburbs of Córdoba

As noted, the fact that ancient cities remained in occupation after the conquest has not been interpreted by those authors that have studied them as a result of continuity (Gutiérrez Lloret 1998, 2012). The documented changes in these cities radically modified their structure and urban physiognomy and have been interpreted as a symptom of a break with the urban past, reflecting a new society, very different from the original. The most typical example is Córdoba, capital of al-Andalus, which experienced spectacular growth, especially in the surroundings closest to the location of an intricate network of recreational houses or suburbs. Some of these have been the object of archaeological intervention, which has allowed us to bring to light a large portion of the city, with planned urbanism, probably a result of the arrival of a new population attracted by the conversion of the city into the residence of amiral and caliphal power. Transformations can likewise be observed at a smaller scale in the other aforementioned cities.

Some cities emerged as a result of the evolution of a more or less complex rural space. One of the most well-studied examples and the current object of an ambitious research project is Madinat Ilbira (Granada). This city, located just a few kilometers from Granada, is currently buried. Recent archaeological interventions indicate that it originated from a group of distinct dispersed nucleations (Fig. 6) (Malpica 2006, 2013).

Thus, the cities of al-Andalus again show the huge changes produced in the settlement network over the two centuries following the Arab-Berber conquest (as seen above in the case of the fortifications). They highlight the milestones of the process by which Andalusian society was transformed, not in itself dissimilar to that observed in other Islamic areas (Guichard 1998).

Spain and North Africa: Islamic Archaeology, Fig. 6 Location of Madīnat Ilbīra, Atarfe, Granada (Malpica Cuello 2013: 20)

Cities, in any case, did not remain unchanging through the Andalusian period. Various authors have considered the evolutionary process of the urban context in recent times, presenting a descriptive and explanatory scheme of its forms of growth and topography (Navarro and Jiménez 2007). A great increase in urbanization occurred during the eleventh and twelfth centuries, lasting until the end of the Middle Ages, during the Nasrid era, when certain specific and differentiated characteristics developed, just before the definitive conquest of the Peninsula by Christians (Malpica and Garcia 2011).

As in the Iberian Peninsula, urban archaeology is one of the most developed areas in North Africa (Cressier 2012). The cities of Ifriqiya and the Maghreb, as indicated, had survived with some strength during the first medieval centuries, in spite of being occupied by Vandals and Byzantines. The Arabs occupied these cities, privileging some over others or founding new centers as in the case of Qayrawan (670). The present urban forms maintain a direct relationship, as happened in al-Andalus, with the structure of this new tribal society. This society assumed a protagonistic role with consolidating elements such as the mosque and the palace, the seat of power, which as political center acquired major dimensions (Guichard 1998). These cities based their growth and strength on cultivation of the land, converting themselves into nuclei receiving the rural surplus (Boone and Benco 1999). Thus, a dense network of cities of various dimensions was established and hierarchically organized. The transfer of trade routes for ivory, slaves, and sub-Saharan gold from the eastern edge of the desert to the west impacted on this urban network, creating various ideal spaces for the establishment of cities linked to the commerce of these goods, while the old centers linked to agricultural cultivation suffered notable decline (Boone et al. 1990). Ceramics found in various archaeological excavations have shed light on this process (Redman 1983–1984), especially in the settlement of Qsar

el Seghir, in the north of Morocco (Redman 1986), Ceuta (Hita and Villada 2003), Sijilmasa (Taouchikht 1996), and Túnez (Daoulatli 1978). The pattern can equally been seen in the north of Morocco, in the mountains of Rif, where, following a broad and extensive program of archaeological surveys, it has been observed that the urban centers that emerged in the interior maintained close links with the rural communities of their hinterlands, for the most part occupied by Berbers. The rise of Almoravid and Almohad power, which extended through the Maghreb and the Iberian Peninsula, contributed to the emergence of port cities on the northern coasts of Morocco (Cressier 1992).

Material Culture: The Production of Ceramics

Another development of recent decades in the Peninsula has been the study of the ceramic production. Great advances in this research took place at the end of the 1970s, when G. Rosselló (1978) published the results of studies on the ceramics of Mallorca. This signified a substantial revision of the field, acting as a catalyst for countless subsequent publications in conference proceedings and specialist journals that offered an overview of ceramic production in al-Andalus. Initially, the primary concern of researchers was to construct a new analytical methodology specific to these materials and to create a morphological corpus. This established a firm basis from which successive studies have been launched.

Within only a few years, particular aspects of analysis began to emerge and develop. One of these concerned the ceramics of the first Andalusian era. The work of S. Gutiérrez (1988) in Eastern Spain produced a group of material previously unknown in scientific literature, which was given the name "paleoandalusı" ceramics. These comprised a group of crude, handmade, or wheel-turned ceramics that in many cases show mixed characteristics. Chronologically, the group is placed during the eighth and ninth centuries in the early Andalusian period and has been interpreted by archaeologists as a manifestation of this transitional amiral period. Similar wares have been documented in North Africa of the same date.

It was not until the consolidation of the caliphate that glazed or varnished material of eastern origin appeared (Cano 1996). Thereafter, we see a diversification of forms, the development of specific functional groups (table ceramic, cooking and storage wares, etc.). Well-formed and well-fired ceramics with complex finishes indicate the establishment of production centers in al-Andalus, with complex techniques applied in each phase of manufacture (selection and manipulation of clays, turning, coating, and firing). This resulted in a new economic and social context. The materials created in these new workshops, located in urban centers of medium and large size, were widely distributed throughout al-Andalus, although it would be the eleventh and twelfth centuries before they reached the last corner (Fig. 7).

At this time, and during the last Andalusian centuries, ceramic materials in various forms reached the highest levels of technological sophistication, both as highly decorated luxury pieces and as domestic utensils (Fernández 2008; García Porras 2006b). These products, of high formal, decorative, and technological quality, would be the object of regular trade throughout the twelfth, thirteenth, fourteenth, and fifteenth centuries when the commercial processes of the West were

Spain and North Africa: Islamic Archaeology, Fig. 7 Dish of Madīnat Ilbīra, Atarfe, Granada (Malpica Cuello 2013: 131)

Spain and North Africa: Islamic Archaeology, Fig. 8 Gazelle vase, Alhambra Museum, Granada (Villafranca Jiménez 2006: 135)

developing (Fig. 8). High demand for these articles explains the frequent appearance of Tunisian and Andalusian materials in eastern contexts and in various faraway places (Italy, France, England and the Northern and Baltic Seas, etc.). In the Nasrid period, the impact of this trade on ceramic manufacture is clearer, with the production of luxuries becoming to some extent detached from that of domestic products. It was during this period that the ceramic artworks known as the "jarrones de la Alhambra" (vases of the Alhambra) and the tiles that decorated Nasrid palaces were created (García Porras 2006).

Future Directions

It should be noted that medieval archaeology in al-Andalus and the Maghreb exhibits very uneven levels of development. In North Africa, archaeological research still lacks depth in some of the areas outlined above (material culture, rural settlement, exploitation of resources, etc.), requiring a greater volume of basic studies. In al-Andalus, research is developing along new lines as some existing fields of study show signs of exhaustion. Among those aspects that show promise for future development, we should highlight landscape archaeology, material culture studies (especially underdeveloped aspects such as archaeometrical analyses), the archaeology of production, the archaeology of agriculture, zooarchaeology, etc. All these fields of investigation, as yet largely unexplored for the medieval Iberian Peninsula and North Africa but on which there are already publications of interest, offer enriching perspectives on historical and archaeological research.

Spain: Archaeological Heritage Management

Amalia Pérez-Juez
Department of Archaeology, Boston University, Boston, MA, USA

Introduction and Definition

After the fall of the dictatorship and the adoption of a democratic political system in 1977, Spain was divided into different regions called autonomous communities. These regions are responsible for managing the archaeological heritage located in their territory, and although there is a national framework law – *Ley de Patrimonio Histórico Español*, LPHE – dating to 1985, each one of them has since passed its own legislation. The way that heritage is defined in these texts, using different adjectives such as cultural, historic, and artistic-historic, has implications for the way archaeological remains are considered and preserved. Ultimately, the regional government decides the general policy and actions that are very much related to their general political tendency in a specific region. For instance, if a region has its own language (e.g., Cataluña or Galicia), the archaeological policy will emphasize local and indigenous sites rather than more recent ones or those that deal with a more homogeneous idea of culture, i.e., the Roman period.

The main responsibilities of the Spanish central government with respect to archaeological heritage management, through its Ministry of Culture, are the looting of sites and the export/import of cultural property (LPHE 16/85, article 6b). This issue has become a very sensitive one since the ratification of the Treaty of Maastricht in 1993, which opened up the borders between the European Union member states. If goods can travel freely throughout Europe, does that include archaeological heritage objects as well? The Spanish law is very clear about this: it is forbidden to export archaeological objects more than one hundred years old or inscribed in the General Inventory of Movable Property (*Inventario General de Bienes Muebles*) without authorization from the Ministry of Culture (LPHE 16/85, articles 5.2 and 30). But then again, what do we do with Spanish Civil War remains (1936–1939) found during an archaeological excavation that are younger than a hundred years old? Are they not eligible to receive the same protection? Some of the regional governments have passed their own legislation regarding this issue, and there is a very engaging intellectual debate about using age as a means to catalog, and therefore protect, archaeological remains (Pérez-Juez 2012).

The other principal contribution of the LPHE 16/85 is the creation of different databases, registers, and legal instruments that provide protection to situations and cases forgotten in previous legal frameworks. Among the new legal instruments, the main one is the BIC – *Bien de Interés Cultural* – that could be translated as property of cultural interest (LPHE 16/85, arts. 9–13). It is a narrowly defined tool which, after compliance with a specific administrative procedure, becomes the subject of very strict protection. The concept of BIC has given rise to doubts and has not prevented the destruction of heritage not listed in the inventory or any of the rest of the categories created in the law (Perez-Juez 2006).

Key Issues

The new regional administrative model, which transferred almost all cultural responsibilities to the regions, has led to an increased investment in local archaeological sites. Since the first decades of its implementation, investment was focused primarily in those sites that deal with indigenous cultures from before the Roman arrival (Celts in the north or Iberians in the east). Issues of identity and the desire to promote a decentralized political and administrative system influenced the sites that were chosen to be excavated and opened to the public. This policy has resulted in the restoration and interpretation of numerous archaeological sites throughout Spain, many of which are difficult to preserve but necessary to foster local involvement and community awareness. Some of the sites have also been grouped in itineraries or routes that integrate different regions, promoting the touristic side of archaeology. The "Via de la Plata Route," The "*al-Andalus*. Routes: the Andalusian Legacy," or The "Iberian Route" are some good examples of the regional governments' goal to preserve archaeological heritage within a more inter-regional landscape (Fig. 1).

The regional governments have created diverse ways of preserving and managing their archaeological remains, but all are based on the idea that heritage belongs to the entire community, despite location on private or public land. This means that any archaeological site must be open to the public if deemed necessary by local authorities. Landowners of the site are also obliged to preserve it, and the destruction of archaeological remains, even those on private land, is a crime that is already generating some interesting legal verdicts. In this regard, the destruction of part of the Phoenician/Carthaginian necropolis of Puig des Molins, Ibiza, by private constructors provides the best – and first – example of a court decision for crimes against cultural property. In 1994, the final verdict sent the defendants to jail as well as condemned them to the payment of three hundred and fifty million pesetas, or 2.103.542,37 euros (Costa et al. 1996). This decision established a precedent for future cases and finished with the impunity that crimes against heritage had enjoyed for a long time.

Sites on public land can be managed both privately and publicly. This choice is generally made with regard to the specific location of the site, i.e., near a tourist center, in a place with easy

Spain: Archaeological Heritage Management, Fig. 1 Talayotic site in Menorca. This Iron Age settlement is a good example of recent monumental sites excavated and restored in order to incorporate them in tourist itineraries. In this case, Menorca, one of the Balearic Island, receives a high number of tourists that visit restored archaeological sites during the summer

access, close to a big city, etc. As tourism is Spain's most important industry, there has been an important effort to restore and present some monumental sites located near coastal tourist regions. Therefore, Roman and Islamic sites, e.g., Ampurias, Segobriga, or Madinat al-Zahra, with their beautiful architecture, have been the main focus of public investment. However, a renewed interest in prehistoric sites and local cultures has resulted in the restoration and interpretation of non-monumental sites in the last few decades. This is the case for all the caves in northern Spain with rock art (Cueva del Castillo, el Pendo, Covalanas, or Tito Bustillo) and other sites with Paleolithic remains like Atapuerca.

European Union Legislation

In addition to the division of the country into regions, one of the recent major forces of archaeological heritage management has been the compliance of Spanish legislation with that of the European Union. The main piece of legislation is the Council Directive 97/11/EC of 3 March 1997, amending Directive 85/337/EEC of 27 June 1985 on the assessment of the effects of certain public and private projects on the environment, generally known as EIA (environmental impact assessment). These directives have been transposed into Spanish national law in the *Ley 6/2001, de 8 de mayo (BOE n° 111, de 09.05.01)*. and Real Decreto Legislativo *1/2008*, de 11 de enero.

This piece of legislation is based on the principle of preventive action and requires, among other things, that archaeological investigation occur before any new construction proceeds, either private or public. The construction of the high-speed train system, airports, and other types of infrastructure has generated numerous archaeological excavations that have yielded an abundance of archaeological data that need to be preserved and studied. The challenge is where to store and exhibit these millions of pieces, whether to build or expand museums or other cultural institutions, and the means to curate the new collections. Public authorities are responsible for seeking out ways of storing, preserving, and showing all the materials that come from the removal of tons of deposits, but in most cases, it becomes a question of budget and space. Some regions, like the Balearic Islands, are assessing their own ways of dealing with this material that has been produced by the economic growth of Spain. Purging some of the findings is one of the proposals on the table, which entails both positive and negative aspects, but might be against the general idea of preserving the past (Fig. 2).

Spain has ratified almost all of the conventions on archaeological heritage preservation and management (e.g., Lausanne, Malta). However, these documents are not always enforced and in many cases they are an indication of the most common practices or remain pure inspiration for internal decisions. In other words, the recommendations made in these conventions will not always be enforced by national or regional policies.

Current Debates

Despite all the new challenges that democracy, economic growth, development, and new European legislation have brought to Spanish archaeological heritage management, the future looks promising. Thanks to the investment in research, restoration, and opening of sites, there has been an increase in public awareness and, therefore, community involvement and private investment. Foundations, local associations, and even corporate engagement are changing the way in which we look at the entire preservation and enjoyment of our heritage. Research has also benefited from this change and new projects are focusing on non-monumental sites. In fact, projects that include research and public outreach are the ones being most supported both by public and private institutions (Pérez-Juez 2010).

A good example of such a joint venture is the project on the paleoanthropological sites of Atapuerca, Burgos, included on UNESCO World Heritage list because of the importance of its fossils for the study of human evolution. In this amazing site, fossils belonging to three different hominin species (*Homo antecessor*,

Spain: Archaeological Heritage Management, Fig. 2 El Cerro de la Gavia, Madrid. This Iron Age site was discovered and excavated during the construction of the high speed train tracks in the outskirts of Madrid. The excavation was paid for by public works funds

heidelbergensis, and *sapiens*.) have yielded important information about the arrival of humans in Europe and their survival and adaptation in the last 1.2 Ma (Arsuaga et al. 2003).

As it relates to heritage management, the sites of Atapuerca have inspired a dual management strategy in which public outreach is equally as important as scientific research, and public outreach programs partially fund research while also promoting community awareness and support. Atapuerca's administration structure involves many entities, including a foundation dedicated to managing private funds and providing legal status to the project. There are also visitor centers, an experimental archaeology park, a research center, and a museum, all of which have promoted the sustainable development of the region, helped to preserve the site, and engaged the community in its preservation.

In 2007, the regional government of Castilla and León (the autonomous community in which Atapuerca is located) created the legal instrument of "Cultural Space" in order to provide a better management framework by expanding the protection of the area beyond the actual sites. In 2009, this same government developed a specific management model with the idea of protection but also of making the sites the epicenter of an economic development in the region: the "Atapuerca System, Culture of Evolution." The Atapuerca System has implemented a more coherent way of managing different bodies and institutions providing a common goal: preservation and sustainable development of the region. It includes most of the abovementioned infrastructure: visitor centers (existing and new ones), the National Center for Research on Human Evolution (CENIEH), the Human Evolution Museum, and others. This integrative formula is new to Spanish heritage management but reveals a current trend that will probably become very successful in the near future (Figs. 3 and 4).

Finally, the recently approved "Historical Memory Law" (2007) has raised new questions about archaeological heritage because the excavation of burial sites, bunkers, trenches, battle fields, and other remains from the Spanish Civil War unearths archaeological material that must not only be preserved but also interpreted, displayed, or reburied. The challenge for managing this new heritage not only concerns preservation but also deals with family stories and

Spain: Archaeological Heritage Management, Fig. 3 Atapuerca site, Burgos. Atapuerca is a good example of a scientifically productive site combined with a very intense public outreach program. In fact, some of the funding comes from private donors that request specific outreach activities for their companies

Spain: Archaeological Heritage Management, Fig. 4 Atapuerca: archaeological summer camps. School kids identifying animal bone. The archaeological camps were developed by the Atapuerca Foundation as part of the public outreach program

political messages that can be sent along with the historical information. Although the method used is clearly archaeological, there is still some debate about the remains being unearthed – bullets, water bottles, buttons, buckles, or even guns –some of which will end up in museums and some of which will be reburied, namely, human remains (Fig. 5).

Future Directions

The management of archaeological heritage in Spain has evolved from the idea of protecting only beautiful monuments in the nineteenth century to a very broad understanding of what archaeological heritage means. New legal instruments to protect both movable and nonmovable heritage

Spain: Archaeological Heritage Management, Fig. 5 Excavated Civil War remains in the Madrid region (1936–1939). These trenches were excavated during the construction of the high speed railway, as part of a contract archaeology project, and shed light on a very important historic period that had not received any attention before the end of the 20th century

are key for the future, as regional governments gain more responsibility and decentralized policies seem to dictate the actual actions. The challenge for the twenty-first century is to harmonize all the existing legislation – regional, national, and international – and enforce it in a way that brings research and public outreach together.

Another important challenge for the twenty-first century is the revision of the legislation that deals with fiscal incentives in the research and preservation of cultural heritage. The current Law of Patronage approved in 2002 (Ley de Mecenazgo 2002) is short on benefits given to private investment and does not really promote private engagement.

Finally, the new approach to archaeological heritage management within a specific landscape, tightly linked to a community that takes into account all the stakeholders around it, is probably the main idea for the future. Some new challenges arise from this holistic vision of heritage, such as the sustainable development of a region, social cohesion around it, or the construction of an identity. Archaeological heritage management, then, becomes a cultural, social, economic, and political tool that needs some cautious understanding. Heritage can foster a very unique feeling of cohesion within a territory that implies a need and a challenge to use this as a means to preserve and study a site, not to use it as a political weapon (Pérez-Juez 2010).

Spain: Nationalism and Archaeology

Margarita Díaz-Andreu
Departament de Prehistòria, H. Antiga i Arqueologia, Facultat de Geografia i Història Universitat de Barcelona, ICREA-University of Barcelona, Barcelona, Spain

Introduction and Definition

Spain is a nation of nations. It was not always so and this is not an assertion that everybody would agree with. However, it better describes today's political reality than any other possible model. In this entry, the relationship between archaeology and nationalism in Spain will be analyzed, paying particular attention to how this has changed over the last 200 years.

Nationalism is based on the idea that "humanity is naturally divided into nations, that nations are known by certain characteristics which can be ascertained, and that the only legitimate type of government is national self-government" (Kedourie 1993: 1). Although this definition seems to indicate a direct relationship between one nation and one type of self-government, in practice the way in which these two concepts are connected is very flexible and there is a wide range of options on how this link is modelled. At one extreme, it is possible to find nation-states such as the Czech Republic in which a single national feeling exists. In contrast, other nation-states have followed a very different model, and in them several nationalisms exist side by side, complementing another level of nationalism. One example of the latter is the United Kingdom of Great Britain and Northern Ireland, formed by England, Scotland, Wales, and a fourth more problematic nation, Northern Ireland.

In the last two centuries, Spain has moved from one model to the other. The debates about the nature of nationalism in Spain are not unrelated to the development of archaeological practice in the country. These debates are in the background of archaeologists, work. At the same time, new proposals archaeologists make impacts the way in which the nature of nationalism is perceived but through this work archaeologists are also involved in these debates, thus becoming active participants in the negotiations shaping the future of the nation.

Historical Background and Key Issues

Christopher Columbus' arrival in America in 1492 thanks to the sponsorship of the Catholic Monarchs was the beginning of a series of historical events that turned Spain – or, more accurately, the different kingdoms on the Iberian Peninsula reigned over by the Catholic Monarchs and their descendants – into a mighty early modern empire. After many decades of decadence, the opportunity created by the Napoleonic invasion of Spain (1808–1814) was seized by many colonies to proclaim independence from the metropolis.

Spain thus entered the nationalism era as an impoverished country with only a few remaining colonies. Before this, from the sixteenth to the eighteenth century, Spanish antiquarians had actively shared the interest of much of the Western world in the classics and classical archaeology. Excavations of Roman monuments and the search for statues, inscriptions, and coins dominated this research. It was combined with an interest in their own national past, as reflected in Ambrosio de Morales' *Relaciones Topográficas* (1575, 1578). The monumental past left behind by the major civilizations in the Mesoamerican and Andean areas was also the focus of attention of both Spanish and local scholars. Information about American ruins had been known since the sixteenth century, and some archaeological monuments, including Palenque in Mexico, were excavated at the time partly thanks to royal funding. The language of the past became a new way of expressing power, abandoning in this way the religious discourse.

The end of the Enlightenment saw the first signs of the regulation of antiquities within the framework of the creation of the modern state. From 1752 the Royal Academies of History and of Fine Arts had been in charge of archaeological excavations and the Academy of History proposed the first ban on the illegal export of antiquities in 1779. The law passed in 1803 to protect monuments and antiquities would be in place for a century, despite the Napoleonic invasion and the many political changes in the history of Spain.

Nineteenth-Century Archaeology in Spain and Nationalism

Spain satisfied the four criteria that nations had to fulfill to be accepted as such (Hobsbawm 1990: 18). The first was the threshold principle, by which only states dominating large territories could qualify as nations. This principle allowed countries such as France, Britain, and Spain to be considered as nations and included others in the Americas, such as the United States and the new countries born out of the decolonization of Latin America. Spain also met the other three criteria: having a long-established elite with a literate and administrative vernacular, having the ability to conquer, and being a historical state (Hobsbawm 1990: 37–38). It was this last condition that convinced politicians and learned individuals all over the Western world of the importance of history and archaeology. Archaeology was – and is – important to nationalism, because by definition nations have a past. This past is constructed through a narrative with data coming from archival documents, philological genealogies, and antiquities. Archaeology, therefore, was one of a range of disciplines that fed national history and national identity. However, in the nineteenth century, the professionalization of archaeology was only partial, as there was a widespread belief in the preeminence of historical documents over material culture remains. At that time, therefore, most scholars dealing with antiquities generally earned their living by other means and satisfied their curiosity regarding the historical roots of their nation in their leisure time. Spain was no exception to this.

King Fernando VII's death in 1833 brought to an end the attempt to continue with the Ancient Regime status quo that had begun with the defeat of the Napoleonic troops in 1814. The modernization of the country led to the dissolution of the monasteries as a way of controlling ecclesiastical power. This involved a change in the ownership of many buildings and in some cases of large territories previously owned by the Church, as well as a sudden increase in the number of antiquities and works of art in circulation. All over Spain two types of institution were set up to deal with this situation: provincial museums and Provincial Commissions for Historic and Artistic Monuments (Comisiones de Monumentos Históricos y Artísticos). The responsibility of the latter was to care for and protect buildings, monuments, and artistic objects that, because of the "beauty of their construction, their antiquity, their origin, their particular use or the historical memories (recuerdos) they impart," should be preserved (Royal Order 2 April 1844). The first learned archaeological societies, including the Spanish Academy of Archaeology and the Archaeological Society of Tarragona, were also founded during this period. Antiquities were also discussed in

new learned journals such as *El Artista* and *Semanario Pintoresco Español*.

The building of the modern state went one step further in 1856 with the establishment of the Higher School of Diplomacy (ESD, Escuela Superior de Diplomática), set up to educate archivists, librarians, and museum curators (first called antiquarians and then, from 1900, archaeologists). This school would be the main learning center for professional archaeologists until 1900, when its lecturers were integrated into the mainstream university system. Most of those taught there went on to work in museums and also children's secondary schools, and from their posts many engaged in archaeological activities and published in the journal related to the ESD and the professional body for museum curators, archivists, and librarians.

In addition to this institutionalization, the influence of nationalism on Spanish archaeology can be seen in the geographical areas and fields of research and the interpretations proposed. The dominant Madrid-based model of Spanish nationalism, which emphasized the Castile-Andalusia axis as the embodiment of the Spanish national spirit, was clearly reflected in the first major national history, Modesto Lafuente's *General History of Spain* (1850–1867), which would become a key factor in the formation of a Spanish national consciousness. Lafuente's work stressed a series of heroes such as the native Viriatus, one of the "unschooled warriors that Spanish soil has always bred" (Lafuente 1850: 22). It highlighted the heroic resistance of Saguntum and Numantia against the Romans but also showed pride in the Spanish contribution to the Roman Empire. However, Lafuente's account of the medieval period occupied many more pages than those devoted to the previous epochs, giving pride of place to the reconquest of the Christian kingdoms in the territory under Muslim rule. The discourse so well expressed by Lafuente and followed by most contemporary scholars was not however devoid of contradictions. Together with the emphasis on Christianity as a key element in the Spanish spirit came a penchant for the reminiscences of Islamic Spain, including Andalusian folklore and Islamic monuments and antiquities. There were also contradictions regarding earlier periods: whereas Roman ruins were perceived as the embodiment of the pedigree of civilization on Spanish soil, the protohistoric deeds of the Celtiberian town of Numantia were hailed as an early demonstration of the brave and resilient character of Spaniards.

The unification of Italy in 1860 (completed in 1870 with the inclusion of Rome) and Germany in 1871 made it much more acceptable for previously divided territories to claim a common ancestry and to be recognized in the international arena as such. Importantly for Spain, the key role played by the vernacular language in both Italy and Germany also made it conceivable for areas that already formed part of a nation-state, but in which a different language was spoken, to claim their right to political independence. In Spain such areas existed in the most developed industrial regions including Catalonia and the Basque Country (as well as in less prosperous areas such as Galicia, the Balearic Islands, and the Valencian Country and in many other areas of Spain where peasants spoke dialects that were not easy for Spanish speakers to understand). Barcelona, and to a great extent also Bilbao, became culture hubs and in them cultural and social elites developed a sense of a separate ethnic identity. Alternative versions to Lafuente's unitary understanding of Spain emerged, all of them stressing the plural nature of the Spanish nation. Catalan historians delved into one of the most important periods in their own history, the flourishing Middle Ages, and recalled Catalonia's role in the reconquest. The attraction towards the Catalan past as a whole was reflected in the appearance of learned societies whose interests covered not only the province of Barcelona but also the four Catalan provinces and, to a great extent, all the areas of Spain where Catalan was spoken, including the Valencian Country and the Balearic Islands. Examples of these learned associations were two rival Catalan Societies of Excursions established in 1876 and 1878.

Professional archaeology, however, was still directed from Madrid: official training continued to take place at the Madrid-based ESD and the National Archaeological Museum, opened in 1867, had the largest number of professional archaeologists. The areas in which scholars

undertook their studies were revealing – whereas throughout the Spanish territory scholars limited themselves to studying the antiquities found in their own provinces (or language areas as in Catalonia), Madrid-based archaeologists managed to deal with the whole of the Spanish territory, thus mirroring the centralized administration of Spain. Interestingly, most of the studies undertaken by members of the National Archaeological Museum dealt with antiquities from Castile and Andalusia.

Monarchy, Republic, and Dictatorship: The Changing Context of Archaeology in the Twentieth-Century Spain

The twentieth century started in Spain with a sense of gloom –Prime Minister Cánovas had been assassinated in 1897 and the last colonies of the once mighty Spanish empire had been lost the following year. The Spanish role in the scramble for Africa had also been minimal. Politically, however, the regime created by Cánovas in 1875, the Restoration, continued seemingly unaffected for two more decades until 1923. Thus, Spanish politics remained anchored in a *caciquismo* that systematically riddled parliamentary elections and allowed the two major parties to alternate in power. However, this status quo was increasingly challenged, especially by the growth of Catalan and Basque nationalism. A mixed formula was proposed, particularly in the case of Catalonia, where it was not necessarily independence that was being sought but self-rule within a Spanish federal state.

Catalan nationalism had emerged in the last third of the nineteenth century, beginning with a strong sense of regionalism that was increasingly transformed into nationalism. In his seminal book, *The Catalan Nationality* (1906), the Catalan politician Enric Prat de la Riba claimed that the origin of the Catalan nation lay in the pre-Roman Iberian peoples who spread over the whole area where Catalan was spoken, from Murcia to the Rhône. He suggested that even then a special phonetic system seemed to indicate the distinctiveness of the language spoken at the time in comparison to neighboring areas. The Roman conquest had regrettably meant the disappearance of the Iberian peoples, whose ethnos would only be revived during the medieval period.

The new atmosphere in Catalonia encouraged the institutionalization of historical and archaeological research. The Institute for Catalan Studies (Institut d'Estudis Catalans, IEC) was founded in 1907. Its remit was to investigate everything to do with Catalan culture, language, and history and its sections included one for archaeology. One of its founders and presidents, the architect Josep Puig i Cadafalch, began the excavation of the ancient Greek colony of Emporion, seen as the origin of the superior intellectual prowess of the Catalan nation in comparison with other areas of Spain. In 1917 Puig i Cadafalch succeeded Prat de la Riba as president of the Mancomunitat de Catalunya, a limited form of self-government enjoyed by Catalonia between 1909 and 1923. Both the Mancomunitat and the excavations in Emporion came to an end with the imposition of General Primo de Rivera's dictatorship (1923–1930).

Also associated to the IEC was Pere Bosch Gimpera. He became interested in archaeology while in Germany on a training grant and was given the first chair in the field shortly after his return in 1916. Significantly, his Ph.D. dealt with the Iberian culture. Until he had to leave Spain and go into exile in 1939, he was able to develop the teaching of prehistory at the university and form a group of students – mainly Pericot, Castillo, and the Serra Rafols brothers – and in 1935 he had also managed to open a museum with collections coming from older institutions. In his writings Bosch Gimpera clearly followed Prat de la Riva in considering Spanish prehistory as a precursor of a multicultural Spain. This thesis was best expressed in his major work *Ethnology of the Iberian Peninsula* (1932).

In the Basque country, the study of prehistoric archaeology was also encouraged, although the main institution was a learned society, the Sociedad de Estudios Vascos (SEV), known in Basque as Eusko Ikaskuntza (Society of Basque Studies). This meant that the three main experts in prehistoric archaeology had to combine their interest in archaeology with the activities involved in their own jobs. Although two of them, Telesforo de Aranzadi and Enrique Eguren, worked in

universities; they taught areas other than archaeology and therefore were not able to train future Basque practitioners of prehistoric archaeology. The third, Father José Miguel de Barandiarán, tried to organize the infrastructure of Basque archaeology from 1916 onwards. He founded the Laboratory of Ethnology and Basque Folklore (Laboratorio de Etnología y Folklore Euskera, in 1916) and the Seminar of Ikuska Prehistory (El Seminario de Prehistoria Ikuska in 1921), later known as the Centre for Prehistoric Research (Centro de Investigaciones Prehistóricas, in 1925, part of the SEV) (Barandiarán 1988: 44). He also fostered the journals Euskalarriaren Alde and Anuario de Eusko-Folklore (created in 1921), which from 1927 included a section on prehistory. Like Bosch Gimpera in Catalonia, Barandiarán stressed a straightforward relationship between prehistoric and modern Basque culture.

Madrid had many more archaeologists than anywhere else in Spain. The university was an example of this. Whereas other universities in Spain had either one chair or none at all, Madrid had one until 1911 and then three: one of Epigraphy and Numismatics for Antonio Vives; one of Archaeology for someone who had long experience in museums and would eventually become the director of the National Archaeological Museum, José Ramón Mélida; and a third of Islamic Archaeology, given to the Andalusian, Manuel Gómez-Moreno. The last two were also involved in setting up a research center, the Center for Historical Studies (Centro de Estudios Históricos). As happened in France, those dealing with the earliest periods of prehistory were involved more in the natural sciences. The person in charge of organizing prehistoric archaeology was Francisco Hernández-Pacheco, Professor of Geology at the University of Madrid from 1910. His alliance with the Count of Cerralbo led to the establishment of the Commission for Paleontological and Prehistoric Research (Comisión de Investigaciones Paleontológicas y Prehistóricas, CIPP 1914). However, during the First World War the exile to Spain of one of the scholars who had held a chair at the Institute of Human Paleontology in Paris, the German Hugo Obermaier, changed the balance of power. Tensions between Obermaier and Hernández-Pacheco led to the creation of a chair of Prehistory for Obermaier at the University of Madrid and the effective isolation of Hernández-Pacheco and the CIPP. Nationalism not only was an influence in politicians', decisions to provide with more funding for the instittutionalization of archaeology in Madrid, as the capital of the Spanish nation-state but also encouraged archaeologists from Madrid to undertake research in the whole of the Spain, unlike their Catalan or Basque counterparts.

The Franco Dictatorship

The tensions of the first three decades of the century resulted in a bloody Civil War in 1936–1939. In contrast to the abuses of archaeology that would take place in both Italy and Germany, in Spain there are relatively few major examples of misuse of archaeological data. This was simply because the periods archaeologists were researching were not part of the nationalist discourse and politicians did not find it necessary to make use of archaeology to the same degree. However, this does not mean that it was not affected. Despite of only three major archaeologists – Obermaier, Bosch Gimpera, and Barandiarán – having to go into exile, a few died and, significantly, all those who remained in their posts had to survive a political purge. The new regime created an office to organize archaeology. This would have been an excellent idea had the person chosen to preside over it not turned out to be highly incompetent. Prof. Julio Martínez Santa-Olalla proved to be a manager influenced by his own likes and dislikes and lived in fear of anybody who tried to overshadow his newly acquired power. He kept for himself and his cronies much of the state funding on excavations. The funds he gave himself were related to archaeological projects about which very little was ever published. He also promoted nonprofessionals by funding their fieldwork while starving those working in universities of much needed funds. As a consequence, a divide was created between

professionals and amateurs, one that still survives today. The anti-Santa-Olalla alliance brought together professors from Madrid (Antonio García Bellido, Martín Almagro Basch), Barcelona (Luis Pericot, Alberto del Castillo) and other young professors from elsewhere in Spain who had trained in Valencia-Madrid and Barcelona (Antonio Beltrán, Juan Maluquer). They were also the ones involved in the International Congresses of Prehistoric and Protohistoric Sciences.

Declarations of support for the Spanish nation as the regime understood it were very explicit, especially in its first years. They came in the form of exhibitions and introductions and prefaces to publications. Alternative nationalisms were hidden under the rubric of regionalism in Catalonia and the Basque Country. To complicate the situation, the professor in Barcelona for the first 15 years of the regime, Martín Almagro Basch, was not Catalan. He trained most of the future generation of Catalan archaeologists and skillfully placed them in the newly created chairs at universities all over Spain. The Catalan professor, Luis Pericot, mainly devoted his time to finding funds to allow others to work. He managed to convince private sponsors (the British and American magnates Leslie Good and William L. Bryant) and also obtained much funding from the American Wenner-Gren Foundation. In the Basque country, Barandiarán returned from exile in 1953 and some institutions were founded, some similar to those mushrooming in other parts of Spain – mainly the Vizcaya Provincial Government Department of Archaeological Research in1958 and the Province of Alava Archaeological Institute in 1966. There were others that focused more on the Basque country, such as the Aranzadi Institute for Archaeological Research (Instituto de Investigaciones Arqueológicas Aranzadi, created in 1962). Archaeology was first taught at a Basque university in 1964.

The Last Forty Years

It has been almost 40 years since the dictator Francisco Franco passed away in his sick bed and Spain went through a relatively smooth transition to democracy. The country is now a quasi-federal state with many of the state areas of responsibility devolved to the 17 Autonomous Communities. Archaeology is, therefore, managed in 17 similar but distinctive ways, each with its own heritage law which is, however, governed by the Spanish Historic Heritage Law of 1985. At first the Autonomous Communities enthusiastically encouraged archaeology in their territories, either in the form of excavations, research, or museum exhibitions. Gradually, however, with the introduction of commercial archaeology, governments began to realize that they could save money by making building contractors pay for it. The loss of politicians' zeal for archaeology may also be related to the way in which the discipline presents its results today – characterized by a high degree of technicality resulting in a distancing of the knowledge archaeologists are producing from the attention of the general public. National histories need an understandable and credible past in the form of a discrete number of archaeological cultures. These are then identified with a particular ethnic group considered as the origin of the modern inhabitants of the nation. This is not what archaeologists write about in their more specialized publications, and consequently both politicians and the general public favor a more "Disneyfied" version of the past. In the current economic climate, it is not surprising that many archaeologists without permanent positions working for the Autonomous Communities and other bodies, as well as in contract archaeology, are seeing their careers curtailed. It looks like we may be entering a new period in the relationship between archaeology and nationalism in Spain.

Spanish Lustreware

Alberto García Porras
Department of Medieval History,
Universidad de Granada, Granada, Spain

Lustrewares are undoubtedly the most outstanding ceramic wares to ever emerge from the Islamic world. The more characteristic feature of lustrewares is their opaque, not transparent, glazing, which was often produced using tin oxide.

Under the generic term Lustrewares, we include a broad group of ceramic and earthenwares, characterized by their tin glaze and a painted decoration. The paints, which were applied in separate firing, were produced using the complex combination of different metallic compounds (the proportions of which varied depending on the workshop and period) and other products such as iron oxide-rich clays, sulfur, and vinegar. After the application of these elements, the piece was fired a second time under highly controlled conditions. The firing had to take place in small kilns, at a low temperature (550–600 °C) and under reducing conditions (the absence of oxygen in the chamber where the piece was being fired), in order for the oxides to retain their metallic nature, especially metallic copper and silver nanoparticles are responsible for the color and shine.

The application of the glaze and the other techniques involved in the production of lustrewares has been the subject of much previous research. In the twentieth century, Oliver Watson (1985), Arthur Lane (1947, 1971), Fehérváry (1973), and Alan Caiger-Smith (1985) analyzed these typologies in detail and included them in their general overviews of Islamic ceramics. These studies, which focused especially on the East, only mentioned Western productions tangentially, although it was clear that lustrewares had also developed in al-Andalus (the regions in the Iberian Peninsula and the Balearic Islands under Islamic rule). Since then, Several Spanish scholars, for instance Balbina Martínez (Martínez Caviró 1982, 1991), have joined the

debate, and more attention has been paid to the Andalusi productions.

Origins of Lusterware

There are two reasons behind the application of opaque glazes on Islamic wares. First, to make them more impermeable so they are better suited to holding drinks or liquid foodstuffs. Secondly, and this is especially applicable to tin glazes wares, to create a white surface as a background for decorative motifs in different colors. These colored paints were made using a combination of a series of metal compounds. The evidence suggests that the production of these sorts of wares started in the East, specifically in the post-Islamic invasion Mesopotamian workshops, following the old glazing traditions in the Islamic East and the Persian Empire. Recent studies have revealed the circulation, along the coasts of the Persian Gulf, and also inland, of porcelains from the Far East. These white porcelains may have encouraged Mesopotamian artisans to find a formula for white glazes onto which decoration could be applied, for example, via opacification of the glaze through the application of tin oxide. Lustrewares were among the first decorative techniques to be applied.

Some lustre on glass can be traced back to Egyptian Coptic and Classical period, but not lustreware ceramics were being produced in Egyptian workshops at that time. The evidence points towards Mesopotamia during the Abbasid period (ninth century) (Fig. 1). The earliest examples have been found in Sāmārra, but there are no known workshops in this city, and thus these productions are assumed to have been produced in Bagdad or Basora. Later, Abbasid ceramics were distributed throughout the whole Islamic world. In Egypt, some lustrewares that predate the Fatimids have been found, but it is not until the triumph of this regime that lustrewares started to be produced in the workshops of al-Fusṭāṭ. The technique was brought there and further developed by a large group of Iraqi artisans. Egypt's central position within the Islamic world played a crucial role in the dissemination and transference of the different

Spanish Lustreware, Fig. 1 Lustreware bowl from Iraq. Tenth century

techniques between the East and the West. The presence of lustrewares has been attested in different North African locations, for example, the still in situ tiles used to decorate the miḥrāb of Sīdi ʻUqba, in Qayrawān (former capital of Ifriqiya, in modern Tunisia), during the ninth century. These tiles were imported from the East; in 862, in fact, a potter from Bagdad was summoned to repair and add pieces to the mosaic, although it is possible that he took his work much further and introduced the technique of lustreware to Ifriqiya, as suggested by some evidence found in Raqqada and Sabra-Mansouriya (Heidenreich 2014: 347; Waksman et al. 2014). In the late tenth and early eleventh centuries, these lustrewares are attested in the nearby Qalāt of the Banū Hammad (Algeria), and in the coastal city of Bugia (Algeria) some decades later.

The emergence and consolidation of these productions followed in the wake of the Islamic invasion in the seventh and eighth centuries, and reflected the integration of the different territories under Islamic rule. Islam was a very extensive empire; it was both diverse and unified, and the presence of these productions in places that played a significant role in the consolidation of the Islamic Empire, such as Qayrawān, Fusṭāṭ, Qalāt of the Banū Hammad, and Bugia is

ideologically meaningful. Their presence cannot merely be interpreted as a reflection of the material demand posed by a given social group but as evidence for the progressive integration of the conquered lands into the Islamic orbit; it is a proxy for the Islamization of the different territories.

Introduction and Earliest Lustreware Production in al-Andalus

Like the Islamic regions in North Africa, al-Andalus was the recipient of a constant stream of Eastern lustrewares from the beginning of Islamic rule. Traditionally, the earliest Andalusi productions of lustrewares were dated to the twelfth century in Malaga (Gómez Moreno 1940) owing to the existence of an assemblage with distinct decorative motifs in the Alcazaba. The earliest written mentions of lustrewares, however, point to other cities, such as Calatayud. The reference is found in the work of the geographer al-Idrīsi (Martínez Caviró 1982: 50). In recent years, as we shall see shortly, this view has been completely superseded, and the earliest lustrewares in the Iberian Peninsula have been pushed back to the ninth century.

As previously noted, the adoption of the technique was preceded by the arrival of a significant volume of imported material. This is for example the case of an assemblage found in Madīnat al Zahrā', the palace-city founded by the Umayyad caliph Abd al-Raḥmān III near Cordoba in the second half of the tenth century. The decoration on these pieces is reminiscent of that found on pieces in Sāmārra, and although the chronologies do not coincide (Sāmārra was the official residence between 836 and 892), everything suggests that the typology and production continued for some time afterwards (Polvorinos del Río et al. 2010). This led to the belief that lustrewares were being produced in the Abbasid city. In any case, we must add that similarity of the Cordoban and Egyptian assemblages have suggested some authors that the pieces found in Madīnat al Zahrā', and similar assemblages found in other palatial or aristocratic sites in al-Andalus, could have a Egyptian origin (Heidenreich 2007: 408).

Some pieces of what is now considered to be the earliest lustrewares in al-Andalus were identified in Seville and its hinterland. These productions include *ataifores* (large plates or bowls) decorated with motifs which are clearly related to Egyptian decorative models; an inscription with golden paint mentions two Abbadid *taifa* kings of Seville – al- Mu'taḍid, who ruled between 1041 and 1069, and al-Mu'tamid, who was king between 1088 and 1092 (Barceló and Heidenreich 2014). These palatial productions started in the mid-eleventh century and must not be understood as an isolated instance, but rather as a reflection of the broader dissemination process of this technique in al-Andalus.

The political fragmentation suffered by al-Andalus after the fall of the Umayyads in Cordoba led to the wider distribution of lustrewares and other green- and purple-decorated wares which, until then, had been restricted to the capital of the Caliphate. Cultural and material features became, upon the disaggregation of the caliphate into multiple lesser polities, mechanisms with which to affirm and legitimise different identities. Although the evidence has not been collected systematically, from the mid-eleventh century onwards lustrewares appear in many *taifa* capitals and other important cities: Zaragoza, Albarracín, Tudela, Onda, Valencia, Murcia, Almería, Malaga, Silves, Mértola, and Seville. The implicit message is that these wares conveyed to the Umayyad capital were now being flaunted by the newly created dynasties. However, during this period these productions were no longer limited to palatial complexes but have also been found in urban centres, castles, and even rural settlements (Ortega Ortega et al. 2014: 316). This seems to point to substantial changes in consumption and demand patterns, and also in scale; the high demand in certain areas appears to have triggered the concentration of workshops.

One city in which the evidence is especially eloquent is Almeria, where excavation and discoveries made in recent decades have revealed the location of workshops and the kind of wares that these workshops produced (Flores Escobosa

2011; Flores Escobosa and Navarro Ortega 2014). Almeria's workshops produced thrown or moulded lustrewares; the evidence indicates that Almeria, which was the caliphate's main harbor because of its strategic position relative to the routes frequented by North African traders, was the point of entry for this and other techniques (García Porras 2014). It is, therefore, not surprising that Almeria was mentioned in al-Aḥmad al-Maqqarī's quote on Ibn Sa'īd: "En Murcia, Almería y Málaga se fabrica vidrio maravilloso y alfarería vidriada y dorada" (Lirola Delgado 2005: 203).

Andalusi Lustrewares

Sometime after the earliest productions in the *taifa* period, in the late eleventh and early twelfth centuries, the lustrewares produce in al-Andalus began to develop their own characteristic features which distinguished them from other Mediterranean productions. Their presence in the Mediterranean markets soon became significant, for example in Pisa, which was one of the earliest Mediterranean commercial powers. The analysis of the so-called "bacini" – plates used to decorate church walls in Pisa – indicate the growing presence of ceramics produced in the Iberian Peninsula in the commercial flows (Berti and Tongiorgi 1981, 1985; Berti 2002b). A good proportion of *bacini* were manufactured in al-Andalus. According to chemical analysis carried out on certain Pisan specimens, some twelfth-century productions come from Murcia (Navarro Palazón 1986; Picon and Navarro Palazón 1986) (Fig. 2). Workshops, however, must have existed elsewhere in al-Andalus, for example, in Almeria. Lustrewares dating to the Almoravid and Almohad periods were characterized by vegetal motifs, such as stalks and leaves, which formed crosses, wheels, etc., or occupied the centre of plates. Often, the main leaves were accompanied by smaller ones. Sometimes, the band around the inner perimeter presented epigraphic, pseudo-epigraphic, or other secondary motifs. On others, to give these ornaments some relief, they were finished with a sgraffito technique, which removes part of the pigment. This technique was well known by the artisans of south-east al-Andalus, who used it to decorate black-painted wares. In addition to the examples from Pisa and Murcia, we must include others from Almeria, Malaga, and Mallorca. An especially interesting example was found in the cave of Amagatalls (Trias 1981), in the Balearic Islands, where a group of Muslims hid their belongings during the Aragonese conquest around 1229.

The first half of the thirteenth century was a period of upheaval, during which al-Andalus lost a good deal of its territory. The eastern coast and the Balearic Islands fell into the hands of the Crown of Aragon, the southern half of the central plateau and the Guadalquivir were conquered by Castile, and the south-west was occupied by Portugal. Al-Andalus was thus reduced to a small kingdom in the south-east of the Peninsula; this kingdom was ruled by the Nasrid Dynasty and was under the political influence of Castile.

Nasrid Lustreware

During the Nasrid period, lustrewares became a key manufacture for the kingdom. From the start, lustrewares were used as a sign of dynastic

identity and political propaganda (García Porras 2012). The Nasrid artisans continued the technical Andalusi traditions, as demonstrated by the blue tiles used to decorate the Cuarto Real de Santo Domingo, one of the dynasty's earliest palaces; such evidence indicates the strong link between the twelfth-century lustrewares and the early Nasrid wares. The vegetal motif with sgraffito is one of their many common features.

The greatest innovation introduced by the Nasrid workshops in al-Andalus glazed pottery was the combination of gold and blue (made with cobalt oxide), combination already known in Syria, Egypt, and Iran workshops from thirteenth century (Pradell et al. 2013, 2016). This combination had already been tried in the East, but was hitherto unknown in the West. For a long time, in fact, it was believed that the introduction of cobalt blue in the Nasrid Kingdom was due to the arrival of Iranian artisans who were attracted by the lustreware industry in Malaga, and their methods, techniques, and decorative models (Frothingham 1951: 21–23). A detailed comparison of the decorative motif used in these initial Nasrid productions and those used elsewhere in the Islamic world suggests, however, that the most direct decorative influences came from Tunisia, not Iran (García Porras 2002) – more specifically from the so-called blue-and-black wares dating to the Hafsid period. These wares had enjoyed some success in Western Mediterranean markets just before the emergence of Nasrid lustrewares (Berti 2002a), and it seems that the Nasrids attempted to reproduce this success with little-known blue-and-black wares and, especially, with the gold-and-blue lustrewares that followed. In this endeavor, based on the evidence available, they were successful, and their wares pushed the Tunisian ones out of the market. It seems likely that this process was fuelled by the agents in charge of the distribution of commercial flows (García Porras and Fábregas García 2010).

All these factors led to the development of a luxury pottery industry in the kingdom in the late Middle Ages, the apex of which was, without doubt, the so-called Alhambra vases – large containers of unknown function (Fig. 5). It is likely that they were simply used to decorate palaces, just like a sculpture (Jiménez and Mar 2006). Undoubtedly, each step of their production, shaping, decorating, grazing, firing, etc. involved highly skilled artisans. Their decoration follows the fashions of the period: geometrical, vegetal, epigraphic, and figurative motifs were used. These motifs were also employed for the decoration of items of table ware, such as large bowls and plates, the most representative examples of which are those from "la nave," currently in the Victoria & Albert Museum (Fig. 3) and the Alcazaba of Malaga, or those from San Jorge, currently in the Metropolitan Museum of Art of New York; other significant examples are the jars in the Instituto Valencia de Don Juan (Fig. 4) or architectural ceramics, tiles and plaques, for example, the so-called Fortuny or the plaque in the Museo Arqueológico Nacional. Many more of these pieces are currently in the Museum of the Alhambra (Flores Escobosa 1988). Since these pieces were representative of the whole ruling dynasty, it is likely that many of them were produced in the Alhambra itself, in the Dār al-tirāz, where production remains have been preserved. In terms of volume, however, the most important productions came from the district of Fontanella, in Malaga, where a number of kilns have been excavated (López Chamizo et al. 2009). It is likely

Spanish Lustreware, Fig. 3 Nazarí Lustreware bowl of "La Nave". Victoria & Albert Museum. Fifteenth century

that Malaga's lustrewares were boosted by the vicinity of the harbor, the most important in the Nasrid Kingdom, from whence these lustrewares, known as "opera di Malica," were distributed throughout the Mediterranean, the Northern Sea, and the Baltic Sea.

As demonstrated by archaeological evidence, the commercial success of the Nasrid lustrewares was short-lived, as they came to be replaced in the markets in the mid-fourteenth century by lustrewares produced in the Kingdom of Valencia (García Porras and Fábregas García 2010: 46).

Mudejar Lustrewares in Valencia

In 1232, following the collapse of the Almohad Empire, James I of Aragón conquered Valencia. After the conquest, many Muslims remained in the territory of the kingdom under the new regime. After a period of economic readjustment, Valencian workshops started producing tin glazed wares in the late thirteenth century.

Lustrewares, however, did not start to emerge from these workshops until the 1310s. These early productions were inspired by Nasrid models (in some Valencian documents we can read *operis terre picte consimilis operis Maleche.* López Elum 1984: 30–33), but the process of the transference of technology that took place between Granada and Valencia is still not fully known (García Porras 2006). The earliest productions, therefore, shared many decorative features with the Nasrid productions from the same period, but the Islamic influence progressively vanished over time (García Porras 2009). This progression can be divided into three styles (González Martí 1944; Ferrer 1988; Lerma and Badía Capilla 1992; Coll Conesa 2009): "Malagueño Primitivo," "Pula," and "Clásicas." The first and second styles used geometric motifs; stars blue or golden in color played a prominent decorative role. "Pula" was named after the Sardinian town, near Cagliari, where the first examples of this style were found (Blake 1986) (Fig. 6). The style is heavily reminiscent of Andalusi models and motifs (tree of life, pinecones, arabesques, schematic epigraphy). The Pula style represents the earliest process of large-scale dissemination of Mudejar ceramics from Valencia, especially the workshops in Paterna and Manises; it is likely that these

workshops soon overtook their Nasrid counterparts in terms of volume of production. Specimens have been found in Sicily, Sardinia, the Italian Peninsula, and Southern France, as well as many other European places. This style declined in the late fourteenth century, giving way to the so-called classic style, which still used some decorative motifs that were similar, although only vaguely, to Andalusi ones, alongside other motifs of a clear Gothic filiation and Western scenes (courtly love, knights, hunting scenes). This was the golden age of Valencian lustrewares, which at that time took the European markets by storm (Fig. 7).

Spanish Lustreware, Fig. 6 Valencian Lustreware albarello (Pula type). Instituto Valencia de Don Juan. Fourteenth century

This process of technological transmission, and the substitution of Valencia for Malaga in the ceramic trade during the fourteenth century, is no more than a consequence of the enormous changes that took place in the economic structures of the medieval West. During these centuries, the center of gravity of the Mediterranean economy shifted from the Islamic areas to the Christian ones.

These ceramic types, which became a must-have for European nobles and burgesses, flooded European markets between the late fourteenth and the early sixteenth centuries, when the Valencian wares began to be replaced by Italian pieces from Gubbio and Deruta. These were decorated using the same techniques and colors, gold and cobalt blue, but with Renaissance motifs.

Spanish Lustreware, Fig. 7 Valencian Lustreware bowl (Clasical type). Instituto Valencia de Don Juan. Fifteenth century

Spanish Modern Lustrewares

In spite of being displaced by Italian wares and their new decorative language, the Spanish workshops continued producing lustrewares between the sixteenth and eighteenth centuries.

Lustrewares were still very important for the workshops in Paterna and Manises (Coll Conesa 2009). Islamic motifs disappeared in the sixteenth century and were replaced by smaller, more schematic motifs, which covered the surface of the plates in repetitive patterns (ribbons, circles, embroideries, flaps, etc.). Some maintained the vegetal theme, but others replaced them with abstract motifs (bushes, thistles, etc.). Very often, these motifs merely accompanied the main themes, which were figurative in nature (crests, animals, natural scenes, etc.).

In any case, the most characteristic novelty of this period was the introduction of relief on the surface of the pieces. Often, relief appears in the form of bulbs and undulations, made with the use of a mould or by pressure, in imitation of metal objects, including the reproduction of small nail heads, bars, or handles. This is the so-called "goldsmith" or "silversmith" style. Other styles are the so-called "cordoncillo," in which the decoration is separated into different fields by thin ropes in relief, the "style of golden bands," "dented leaves," "outlines leaves," etc. (Fig. 8).

In addition to the productions from Valencia, other workshops were also active during this period, for example, in Muel, Barcelona, Reus, and Seville. Generally, the style of the productions emerging from the workshops in the Aragonese town of Muel was reminiscent of that of the Valencian products, although a new independent style developed over time. Relief was not quite as common as in the Valencian examples, and the compositions were less motley; also, the white background has a creamier hue and the golden tones are more coppery (Martínez Caviró 1991: 238).

Catalonian lustrewares emerged in the second half of the fifteenth century, and they were of some importance in the sixteenth century; the main workshops were located in Barcelona and Reus (Tarragona). Like those from Muel, the Catalonian productions were closely related to their Valencian precedents, but again the motifs are more loosely distributed. The workshops in Triana (Seville) also started producing this kind of ware in the late sixteenth century (Pleguezuelo Hernández 2014).

Spanish Lustreware, Fig. 8 Valencian Lustreware bowl (Cordoncillo type). Victoria & Albert Mueeum. Fifteenth–sixteenth centuries

As pointed out by Jaume Coll, the sixteenth century was a century of upheaval for society, marked by the issue of the Moriscos and the forced conversion of the Muslims who had decided to remain in the Iberian Peninsula. The Mudejar presence in the ceramic sector was very significant, and this is reflected in ceramic production. The recurrent presence of religious messages such as "surge domine" or "in principio erat Verbum," indicates the manifest intention of stressing the identity of producers and consumers. A similar role was played by the depiction of human figures and aristocratic scenes with knights and couples, which were forbidden by Islam. Only a few motifs are reminiscent of those used by Mudejar potters in the fourteenth century and are perhaps the manifestation of a residual and hidden Islam (Coll Conesa 2009: 124–125).

From the seventeenth century onwards, Valencian lustrewares went into sharp decline, partially as a consequence of the final expulsion of the Moriscos in 1609 (Martínez Caviró 1982: 175). The disappearance of the lustreware workshops in Muel is generally associated with this event, although it is also possible that "the loss of the technical edge"compared to Chinese porcelain, which was already available in the whole of Europe; the Italian wares and the Spanish wares from other centres, such as Talavera de la Reina, was also related Coll Conesa 2009: 130).

Despite the commotion that the expulsion of the Moriscos undoubtedly caused, during the opening decades of the seventeenth century, the workshops in Valencia and Reus (the latter seems to have taken Muel's baton in the production of lustrewares) remained in operation. Their style continued the traditions of the previous century, for example, with the "l'Ugla" series. It is only from the second third of the century that new, looser decorative motifs emerge, with flowers, bulbs, fern leaves, and, from the mid-century, starry backgrounds, semicircles, and leaves framing the central, figurative scenes, for example the "pardalot." (Figs. 9 and 10)

Many of these motifs, for example, the vegetal ones, survived throughout the eighteenth century, when, under pressure posed by new productions from Talavera de la Reina, Puente del Arzobispo, and Alcora, lustrewares were forced to introduce new decorative motifs, such as rows of ovals, pinks, and poppies.

Spanish Lustreware, Fig. 9 Valencian Lustreware pitcher (Pardalot). Instituto Valencia de Don Juan. Seventeenth century

Spanish Lustreware, Fig. 10 Catalonian Lustreware. bowl. Instituto Valencia de Don Juan. Dated 1599

Thereafter, lustrewares would play a marginal role in Spanish ceramic productions; they were a

relic from a past that were quickly displaced by a new reality. Only the Romantic revival of the second half of the nineteenth century, which recovered some Oriental and Medieval traditions, rekindled lustreware for a brief period of time.

State of Knowledge and Current Debates

Introduction

Spain became a member of UNESCO in 1953. The General Conference of UNESCO adopted the Convention Concerning the Protection of the World Cultural and Natural Heritage in 1972, which came into force in 1975. Spain signed this convention on the 4th of May 1982.

As of August 2017, Spain has 46 listed World Heritage sites before France (43) and Germany (42); only Italy (53) and China (52) have more.

Forty of the Spanish sites are cultural heritage sites, four are natural, and two are mixed. Three sites are shared: one with France, one with Portugal, and one with Slovenia (Spain 2017).

The sites are quite evenly distributed over the whole Spanish territory.

In this entry we will treat only the cultural and mixed heritage sites.

In 12 of the sites, we have as one of the most important features of the heritage property a whole town or city, in 11 sites Roman Catholic religious buildings, in 10 sites civil buildings, in 6 sites a landscape, in 6 sites archaeological remains, in 5 sites fortifications, in 4 sites palaces, in 3 sites prehistoric rock art, and in 1 site an Islamic religious building.

Most sites comprise features from different periods, but in 13 sites the features are mainly from the Late Middle Ages, in 10 sites from the

Renaissance, and in 7 from the Baroque, which means that in 30 sites the features are mainly from the development of the Spanish Empire on the basis of the Kingdom of Castile or of the Spanish Empire itself, the so-called *Spanish Golden Age*. Seven sites are principally from the Early Middle Ages, six sites from Antiquity (five Roman, one Carthaginian), and five from prehistoric times. Six sites developed mainly under Islamic rule between the eighth and fourteenth century. Only three sites are from the nineteenth or twentieth centuries. Most of the 30 sites, where the main features are from the Spanish imperial period, we find in Central and Southern Spain and Galicia, while the three sites from the nineteenth to twentieth centuries are in the Basque Country and Catalonia.

From the 42 cultural sites, 5 were declared in 1984, 5 in 1985, 3 in 1986, 1 in 1987, 1 in 1988, 1 in 1991, 3 in 1993, 2 in 1996, 4 in 1997, 3 in 1998, 2 in 1999, 5 in 2000, 1 in 2001, 1 in 2003, 1 in 2006, 1 in 2009, 1 in 2011, 1 in 2012, and 1 in 2016 (Spain 2017).

In August 2017 there were 29 sites on the Spanish Tentative List for inscription as World Heritage sites (Spain 2017).

The Spanish contribution to the World Heritage Fund was $79,764 USD in 2016 (Statement of Compulsory and Voluntary Contributions 2016).

Alhambra, Generalife, and Albayzín Quarter, Granada

The Alhambra and the Generalife palaces were declared World Cultural Heritage in 1984, and in 1994 the quarter of Albayzín was added. The two palaces were included in the World Heritage list as unique examples for royal Arab residences from medieval Islamic Spain (Advisory Body Evaluation 314 1984, p. 3), while the Albayzín quarter as a typical medieval Moorish settlement with its urban fabric, the architecture, and its main characteristics (form, materials, colors) (Advisory Body Evaluation 314bis 1994, p. 63).

Being for a long time a Muslim stronghold, Granada became the capital city of the Nasrid dynasty, from the fall of Cordoba in 1236 until 1492. During this time the city was embellished with palaces like the Alhambra, and the Generalife and Muslim and Jewish culture flourished in quarters such as the Albayzín.

The Alhambra is a massive fortress enclosed by a wall of 2 km with towers. It includes palaces, gardens, workshops, baths, and a mosque. The palaces are mainly from the fourteenth century and built around two monumental squares. In the buildings we find marble, plaster, wood, ceramics, and leather used in an overwhelming composition for walls, columns, stalactite cupolas, doors, windows, floors, ornamental decoration, and calligraphic inscriptions. Nature, too, has been used lavishly as a decorative element, especially gardens and water in fountains, basins, cascades, and canals, all made possible by highly developed hydraulic infrastructures (Advisory Body Evaluation 314 1984, pp. 1–2).

The Albayzín quarter, on the hill adjacent to the Alhambra hill, exemplifies a typical medieval Spanish Muslim town plan with its narrow streets and Moorish-style houses (Advisory Body Evaluation 314bis 1994, p. 64).

The total World Heritage site expands over 450 ha (Alhambra, Generalife and Albayzín, Granada 2011).

Burgos Cathedral

The Cathedral of Santa María of Burgos was declared World Cultural Heritage in 1984. It was inscribed into the World Heritage as being very influential on the evolution of architecture and the plastic arts through the spread of French Gothic from the thirteenth century in Spain, due to the importance of its workshop and school during the fifteenth and sixteenth centuries with craftsmen and artists from the Rhineland, Burgundy, and Flanders and as model in the nineteenth century. The church and its cloister are seen as important examples of an integral Gothic cathedral (Advisory Body Evaluation 316 1984, p. 3).

The Cathedral was constructed between 1221 and 1567, divided into two phases: the first between 1221 and 1293 following mainly French models and the second from the middle of the fifteenth century undertaken by a very international workshop (Advisory Body Evaluation 316 1984, pp. 1–2).

Historic Center of Cordoba

The Mosque of Cordoba was declared World Cultural Heritage in 1984, and in 1994 the whole historic center of Cordoba was included in this heritage site. The Mosque became part of the list of World Cultural Heritage as an outstanding example of religious Islamic architecture from the caliphate of Cordoba (929–1031) which, with its dimensions and design, had a great influence on western Muslim art and the "neo-moresque" styles of the nineteenth century (Advisory Body Evaluation 313 1984, p. 3). The historic center of Cordoba was added for the same reasons. The World Heritage site now contains an important part of the historic center, the Alcázar, the river Guadalquivir, the Roman bridge, and the Calahorra Tower, a total of 80 ha (Advisory Body Evaluation 313bis 1994, pp. 60–61; Historic Centre of Cordoba 2015).

Cordoba had been an important city since Roman times. It was the capital of Muslim Spain in the eighth century, depending on Damascus, and the capital of an independent caliphate since 929. The city became one of the most extensive examples of a medieval Muslim capital city, with its narrow street network, its Great Mosque (built between 785 and 1009), palaces, dwellings, and a riverport. Having been an important city before and being one of the most important urban and cultural centers of Europe, Northern Africa, and the Middle East from the tenth to the twelfth century, it also reflects the coexistence of three cultures/religions during the Middle Ages: Islam, Judaism, and Christianity.

Monastery and Site of the Escorial, Madrid

The Monastery of San Lorenzo del Escorial was declared World Cultural Heritage in 1984. It forms part of the World Heritage list as an example of human creative genius, the ideological and artistic ideas dominant in architecture, monumental arts, and landscape design during the Spanish Golden Age and common for palace complexes and their urban and landscape design created by the European monarchies. Because of its close association with the Spanish rulers of the House of Austria and the House of Bourbon, it has been also seen as of great importance for European and world history since the early modern times (WHC-14/38.COM/8E 2014, p. 130).

Built between 1563 and 1584, the Escorial was envisioned by the Spanish King Philip II and his architect Juan Bautista de Toledo as the directing center of the Spanish Empire at the apogee of its power in the sixteenth and seventeenth century. It became the muscular declaration of Spanish world power, of the oneness of the Spanish Monarchy and the Catholic Church, an ideological and artistic expression of the Spanish Monarchy and its Catholic kings. This is why it was planned from the start as monastery and royal residence and also as the pantheon for the Spanish kings and queens from Charles V (1500–1558) until today.

The different parts of the Escorial (the monastery, the royal palace, the library, the school, the seminary, the service buildings) are ordered around different courtyards and centered in the basilica. The whole complex is a massive and austere stone building, a quadrangle of approximately 153 m by 224 m, built in the Spanish Renaissance style with latter Baroque incorporations. The Escorial also houses a rich art collection including works from Titian, Tintoretto, El Greco, Velázquez, Paolo Veronese, and others. The complex covers 94 ha (Monastery and Site of the Escurial 2017)

Works of Antoni Gaudí

In total seven works of the Catalan architect Antoni Gaudí (1852–1926) were declared World Cultural Heritage: Park Güell (1904–1916), Palau Güell (1886–1890), and Casa Milà (1906–1910) in 1984 and Casa Battló (1904–1906), Casa Vicens (1883–1885), the Nativity Façade and the Crypt of the Sagrada Familia (1883–1926) and the Crypt of the Colònia Güell (1898–1905) in 2005, all of them located in or near to Barcelona. They were inscribed into the World Heritage list as an exceptional creative contribution to nineteenth and twentieth century architecture and building technology, exemplifying cultural currents of the time, as, for example, the Catalan *Modernisme*. (Advisory Body Evaluation 320bis 2005, p. 173).

Gaudí's work is exceptional for being inspired by traditional and patriotic Catalan ideas, while using the technical progress of modern industry, economy, and society, which also makes him the

most outstanding representative of the Catalan *Modernisme* movement from the end of the nineteenth and start of the twentieth century: the apogee of Catalan culture. He developed a very eclectic style, which draws in a revolutionary way from the different styles from all over the world and different periods, borrowing in a very imaginative and creative manner, all of which only makes his work more universal. He produced a very personal, unique and individualistic synthesis of different literary and artistic movements of his time, such as the Arts and Crafts movement, Symbolism, Expressionism, and Rationalism (Advisory Body Evaluation 320bis 2005, p. 173).

Cave of Altamira and the Paleolithic Cave Art of Northern Spain

The Cave of Altamira was declared World Cultural Heritage in 1985, and the site was extended to 17 more caves (La Peña de Candamo, Tito Bustillo, Covaciella, Llonín, El Pindal, Chufín, Hornos de la Peña, El Castillo, Las Monedas, Las Chimeneas, Las Pasiega, El Pendo, La Garma, Covalanas, Santimamine, Ekain, and Altxerri) in 2008. They were included in the World Heritage list as eminent examples of cave art from the Upper Paleolithic and testimony of the origins of human civilization (WHC.08/32.COM/24rev 2008, p. 182).

All 18 caves lie inside the small strip between the Cantabrian Mountains and the Cantabrian Coast in Northern Spain. The caves preserved on their walls and ceilings astonishingly well depictions of animals (bison, horse, hind, etc.), humans, and signs painted in the period between 35,000 and 11,000 BC, with its high point during the Magdalenian period (17,000–13,000 BC). The depictions are sometimes realistic, sometimes schematic; they are painted with lines, dotted lines, color wash, or spraying; or they are engraved. The dominant colors are ochres, reds, and blacks (Advisory Body Evaluation 310bis 2008, pp. 217–218).

The Paleolithic cave art from this area has its singularities which render it different from other exceptional cave arts of the same period in the Périgord (France), Portugal, Andalusia, and the Ebro Valley.

Monuments of Oviedo and the Kingdom of the Asturias

The churches of Santa Maria del Naranco, San Miguel de Lillo, and Santa Cristina de Lena in the area of the capital of the Spanish region of Asturias, Oviedo, were declared World Cultural Heritage in 1985. The site was extended in 1998 to the Cámara Santa of the Cathedral in Oviedo, the Basilica of San Julián de los Prados, and the Foncalada. These monuments were integrated into the World Heritage list because of their pre-Romanesque Asturian style with the basilica layout, entirely vaulted, use of columns instead of piers, and rich decorations with Visigothic and Arabic elements and forms associable to the sanctuaries of Asia Minor. It is also seen as testimony to the small Christian Kingdom of Asturias existing during the dominance of the Emirate of Cordoba (Advisory Body Evaluation 312 1985, pp. 2–3).

All the monuments were built during the ninth century, when most of the Iberian peninsula was part of the Islamic cultural area, but Oviedo was the capital of the Christian Kingdom of the Asturias, which in Spanish historiography has often been seen as the primal nucleus of what was to become in the sixteenth century the Spanish Empire of the Catholic Kings and the Kingdom of Spain today.

The four churches and the Cámara Santa of the Cathedral of Oviedo are most representative for a pre-Romanesque style which combines elements from classical Rome, Late Antiquity, Paleo-Christian, Paleo-Byzantine, and Visigothic Mozarabic, but also local, designs. The Foncalada is a first-rate example for hydraulic engineering of the early Middle Ages (WHC-14/38.COM/8E 2014, pp. 131–133).

Old Town of Ávila with Its Extra-Muros Churches

The Old Town of Ávila and four churches outside of the city walls were declared World Cultural Heritage in 1985, and in 2007 the site was extended to three churches more and three convents. They were inscribed into the World Heritage list as an exceptional urban ensemble of a fortified medieval city with intact walls and a high

density of religious and secular buildings (Advisory Body Evaluation 348rev 1985, p. 2).

The city of Ávila was in the eleventh century established as a stronghold of the expanding Kingdom of Castile against the Muslim territories to the south. So, it was an important part of the policies of the Kingdom of Castile, what were to become latter Spain, to settle the newly won territories with Christians mainly from Northern Spain.

The walls which surround the Old Town are nearly entirely preserved; they have a length of more than 2.5 km, 82 towers, and 9 gates, all built during the eleventh and twelfth century. The seven extra-muros churches (San Segundo, San Andrés, San Vicente, San Pedro, San Nicolás, Santa María de la Cabeza, and San Martín) are of Romanesque style and from the twelfth century. The three convents (La Encarnación, San José, and the Real Monasterio de Santo Tomás) are from the fifteenth and sixteenth centuries. The total World Heritage site has 36 ha (Advisory Body Evaluation 348bis 2007; Old Town of Avila 2017).

Old Town of Segovia and Its Aqueduct

The Old Town of Segovia and its aqueduct were declared World Cultural Heritage in 1985. They were inscribed as World Heritage site because Segovia and its plenty monuments are seen as historically important and a testimony of a Western city with a social structure where hierarchy was overshadowed by the belonging to one of the different cultural communities: Muslims, Christians, and Jews. This is reflected in the ensemble of its buildings, from domestic architecture to the great religious and military structures, where the most diverse construction techniques and styles are present (Advisory Body Evaluation 311rev 1985, pp. 1–2).

Segovia has been erected on a rocky cliff between two rivers. As a whole, the city is an example of the complex historical reality of Spain during the Middle Ages and early modern times. On this World Heritage site, we find a Roman aqueduct, one of the best preserved worldwide, from the first or second century; the Alcázar built between the eleventh and sixteenth century; the Gothic cathedral from the sixteenth century; Romanesque churches from the eleventh, twelfth, and thirteenth centuries; palaces from the fifteenth and sixteenth centuries; and the Royal Mint from the sixteenth century. The World Heritage site totals 134 ha (Old Town of Segovia 2011).

Santiago de Compostela (Old Town)

Santiago de Compostela Old Town was declared World Cultural Heritage in 1985. It was included in the World Heritage list because of its historic center and its mainly Romanesque and Baroque Cathedral, both cultural and artistic masterpieces and intimately linked to one of the major themes of medieval European history: the pilgrimage to the supposed burial place of Saint James the Greater (Advisory Body Evaluation 347 1985, p. 3).

Since the ninth century, Santiago de Compostela, a town in Galicia in the northwestern corner of Spain, became famous for being the supposed burial place of Saint James the Greater, apostle of Jesus Christ. It developed over the following centuries into the third most important pilgrimage place of all Christianity. Furthermore it became strongly connected to the struggle of Christian Spain against Islam through the legendary figure of Santiago Matamoros (Saint James the Moor-slayer).

Inside the Old Town, we find the cathedral with the Holy Tomb, masterpiece of Romanesque and Baroque architecture, and other buildings in the Romanesque, Gothic, Renaissance, Baroque, and Neoclassical styles, testimony of the ongoing strength of faith. The World Heritage site covers 108 ha (WHC-14/38.COM/8E 2014, pp. 147–148) (Santiago de Compostela 2017).

Historic City of Toledo

The historic city of Toledo was declared World Cultural Heritage in 1986. It was included in the World Heritage list in its entirety as a unique artistic achievement, from Visigothic times to the Baroque of the early eighteenth century, including a Mudéjar style, which combined Visigothic and Muslim elements, and eminent monuments from the fifteenth and sixteenth centuries (Advisory Body Evaluation 379 1986, p. 2).

Located geographically right in the center of Spain, Toledo had been since Roman times an important crossroad and strategic location. It became the capital city of nearly the whole Iberian Peninsula in Visigothic times and was politically and militarily one of the most important places in Spain during Islamic rule and after the conquest by Christians (1085). Until Philip II it was one of the capital cities of Castile and Spain, and until today it was the center of the Spanish Catholic Church.

From Roman times we find in Toledo the remains of a circus, an aqueduct, and a sewer, from the Visigothic period we find parts of the walls, and from the period of Islamic rule, we find, for example, the old Gate of Bisagra, the gate of Bab al-Mardum, the mosque of the Tornerías, and the mosque of El Cristo de la Luz. From after the Christian conquest of the city and the later Middle Ages, we find, for example, two important Jewish synagogues (Santa Maria la Blanca, El Transito), churches (the mainly Gothic Cathedral, the Romanesque San Roman), but also civil buildings like walls, bridges, and houses. We find buildings in Mudéjar style (Santiago del Arrabal, Galiana palace) and, from the fifteenth and sixteenth centuries, the churches of San Juan de los Reyes, San Juan Bautista, parts of the cathedral, and the hospital of the Santa Cruz (Advisory Body Evaluation 379 1986, p. 2).

Toledo was also home to El Greco and houses various paintings of his, the most famous being *The Burial of the Count of Orgaz* in the church of Santo Tomé. The World Heritage site covers in total 260 ha (Historic City of Toledo 2013).

Mudéjar Architecture of Aragón

Four buildings in the city of Teruel were declared World Cultural Heritage in 1986. This was extended to six more in 2001. They were included in the World Heritage list as testimonies of Aragonese Mudéjar art which came out of the coexistence of Islamic and Christian societies after the Reconquest (the conquest of Islamic territories by the Spanish Christian kingdoms) between the twelfth and seventeenth century. It has important influences from the Islamic world and various European styles that developed during the same centuries, particularly from Gothic (Advisory Body Evaluation 378bis 2001, p. 103).

The ensemble includes ten monuments in total: the Cathedral of Santa María de Mediavilla at Teruel, the church of San Pedro at Teruel, the church of San Martín at Teruel, the church of Salvador at Teruel, the church of Santa María at Calatayud, the church of Santa Tecla at Cervera de la Cañada, the church of Santa María at Tobed, the Mudéjar features of the Aljafería Palace at Zaragoza, the church of San Pablo at Zaragoza, and the Cathedral of La Seo del Salvador at Zaragoza. The Mudéjar style appears specially pronounced in the towers, ceilings, domes, and apses of the religious monuments (Advisory Body Evaluation 378bis 2001, p. 101).

Old Town of Cáceres

The Old Town of Cáceres in the Spanish region of Extremadura was declared World Cultural Heritage in 1986. It was included in the World Heritage list as an important example of the fortifications built in Spain by the Almohades during the twelfth and thirteenth centuries and a city which was dominated from the fourteenth to sixteenth century by powerful rival clans with their fortified houses, palaces, and towers which dominate the Old Town today. The city bears witness to very diverse cultural influences as different Islamic styles, Northern Gothic, Italian Renaissance, and arts of the New World (Advisory Body Evaluation 384 1986, p. 3).

In its layout and the churches, palaces, towers, walls, gates, and houses, the Old Town is a typical example of a Spanish medieval city formed on the frontier between Islam and Christianity. The site covers 9 ha (Old Town of Cáceres 2017).

Cathedral, Alcázar, and Archivo de Indias in Seville

The cathedral, the Alcázar, and the Archivo de Indias in Seville were declared World Cultural Heritage in 1987. They were included in the World Heritage list because the Cathedral and its tower (and former minaret), the Giralda, are seen as unique artistic achievements of the Almohad, Gothic and Renaissance styles. Furthermore all three buildings are directly associated with the

discovery of the New World by Christopher Columbus in 1492–1493 and its colonization during the centuries afterward (Advisory Body Evaluation 383rev 1987, p. 3).

The complex of the three buildings together symbolizes in an inspiring way also the essence of the Spanish Monarchy as a world power at its apogee: royal, ecclesiastical, and trading power. The first parts of the Alcázar were built during the tenth century as a residence of the Muslim governor; it became the home of Muslim and Christian rulers and is still today the palace of the Spanish royal family in Seville. It brings together Almohad, Mudéjar, Renaissance, Baroque, and Neoclassical styles. The Cathedral with its five naves is the largest Gothic building in Europe and houses the tomb of Christopher Columbus. Its bell tower, the Giralda, was erected as an Almohad style minaret and is today topped by Renaissance architecture. The building of the Archivo de las Indias, the Lonja, was established in 1585 as a merchants' consulate and houses today the greatest collection of documents concerning the discovery and colonization of the New World (Advisory Body Evaluation 383rev 1987, pp. 1–3).

The site covers in total 13 ha (Cathedral, Alcázar and Archivo de Indias in Seville 2017)

Old City of Salamanca

The Old City of Salamanca was declared World Cultural Heritage in 1988. It was included in the World Heritage list as one of the first places with an important university in Europe. Although not as old as Bologna, Oxford, and Paris, it was already well established around 1250 and conserves an important heritage which bears witness to this. The second important feature is Salamanca's remarkable monuments in the *Churrigueresque* style, a Baroque style of the eighteenth century developed by the Churriguera family dynasty of architects. This style was also exported with considerable influence to Latin America (Advisory Body Evaluation 381rev 1988, p. 3).

The Old City of Salamanca is essentially one of the first university cities of Europe with its roots in the eleventh century and owes to this fact important Gothic, Renaissance, and Baroque buildings from the fifteenth to eighteenth century (the Hospital del Estudio, the Escuelas Mayores, the Escuelas Menores, the Colegio de los Irlandeses, and various other colleges, which multiplied between the fifteenth and eighteenth centuries). It also retains other structures as testimony of more than 2000 years of history, for example, the Roman bridge over the River Tormes, the Cathedral and the church of San Marcos from the twelfth century, the Salinas and Monterrey Palaces from the sixteenth century, and the *Churrigueresque* style ensembles like the Plaza Mayor (1729–1755), one of the most important ensembles of eighteenth century Europe, the Clerecía (the Jesuit seminary), the college of Calatrava, the Colegio San Ambrosio, the churches of San Sebastián and Santa Cruz de Cañizares, the New Cathedral, and San Esteban all from the eighteenth century (Advisory Body Evaluation 381rev 1988, pp. 2–3).

It covers 51 ha (Old City of Salamanca 2017).

The Poblet Monastery

The monastery of Santa Maria of Poblet was declared World Cultural Heritage in 1991. It was included in the World Heritage list as one of the most perfect examples of Cistercian style from the twelfth, thirteenth, and fourteenth centuries. Furthermore Poblet was one of the largest and most complete of the Cistercian abbeys, a military complex, and a royal palace, residence, and pantheon (Advisory Body Evaluation 518rev 1991, p. 3).

The monastery is located in southern Catalonia and was first settled by Cistercian monks in 1153. Most of the buildings were erected during the twelfth to fifteenth centuries. The land had been given to the Cistercian order by the powerful and influential Count of Barcelona, Ramón Berenguer IV, in 1150. For the following centuries, the monastery received many donations from the kings, queens, and nobility of Catalonia and Aragon and served first also as a fortified royal residence and from 1340 as the royal pantheon. The community of monks ended in 1835 but was reinstalled in 1940 (Advisory Body Evaluation 518rev 1991, pp. 1–2).

The monastery is a key example for the repopulation and new agricultural exploitation by Christian kingdoms of former Muslim-dominated territories and a symbol for the ruling houses of Catalonia and Aragon.

The monastery consists of three enclosures all encircled by a defensive wall. These contain the church, cloister and monastic rooms (chapter house, refectory, kitchen, calefactory, library, scriptorium, dormitory), chapels, a hospital for the poor, royal chambers, a guesthouse, the abbot's residence, the prior's lodgings, storehouses, workshops, an oil mill, and housings for lay persons. The innermost enclosure is heavily fortified with battlements, walkways, towers, and an impressing gatehouse. The constructions are built in the Romanesque, Gothic, and Renaissance styles. The most notable features of the church are the royal tombs (Advisory Body Evaluation 518rev 1991, pp. 1–2).

The site covers 18 ha (Poblet Monastery 2017).

The Archaeological Ensemble of Mérida

The Archaeological Ensemble of Mérida was declared World Cultural Heritage in 1993. It was included in the World Heritage list as outstanding example of a major Roman provincial capital (Advisory Body Evaluation 664 1993, p. 52).

Mérida in the Spanish region of Extremadura was founded in 25 BC by the Romans as Augustus Emerita. It became the capital city of the Roman province of Lusitania and was designed after the Roman ideas of an ideal capital city. Later in the third century, it became the capital of all of Hispania. After the fall of the Roman Empire, it was for some time the capital of the Germanic tribes of the Suebi and Visigoths before it fell under Muslim rule.

The archaeological remains of Mérida's past are well preserved, but also monuments from later periods have been included as World Heritage. In total there are 22 sites with their public civil, religious (Roman and Christian), and private buildings, water management infrastructures, and museums: the Milagros aqueduct, the San Lázaro aqueduct, the Alcantarilla Bridge, the Guadiana River Dam, the bridge over the Guadiana River, the Alcazaba, the Roman theater, the amphitheater, the amphitheater house, the Trajan's Arch, the Concordia Temple, the Sta. Catalina Basilica, the Casa Herrera Basilica, the Sta. Eulalia Basilica with its Interpretation Centre, the Temple of Mars, the Roman Circus, the Mithraeum House and the Columbaria Funerary Area, the Church of Sta. Clara and its Visigothic Art Collection, the Cornalvo Dam, the Proserpina Dam, the Forum, the Roman Wall and the Albarrana Islamic Tower, the National Museum of Roman Art, the Sta. Eulalia Obelisk, the bridge over the Albarregas River, the Temple of Diana, the Thermal Baths at Reyes Huertas St., and the Thermal Baths at Alange. The ensemble comprises 31 ha (Archaeological Ensemble of Mérida 2017).

Routes of Santiago de Compostela: *Camino Francés* and Routes of Northern Spain

The Routes of Santiago de Compostela were declared World Cultural Heritage in 1993, and the declaration was extended in 2015. They were incorporated into the World Heritage list as a testimony to the pilgrimage route of St James of Compostela which helped the cultural interchange between the Iberian Peninsula and the rest of Europe in medieval times, which were at the same moment an essential part of European spiritual and cultural life and which still today is a manifestation of the power of faith among people of all classes and countries in Europe during the Middle Ages (Advisory Body Evaluation 669 1993, p. 63).

The Routes of Santiago de Compostela are different routes in Northern Spain which lead about 800 km from the French border (the Pyrenees) to the supposed burial place of the apostle St. James the Greater in Santiago de Compostela, being the Camino Francés (the French route) the main one. The route developed from the ninth century into one of the most important pilgrimage routes of Christianity and persists until today. Established over centuries on the route was an enormous infrastructure to care for the worldly and spiritual needs of the pilgrims and to make the passage possible. We find churches, hospitals, hostels, and civil engineering structures like bridges in the Romanesque, Mudéjar, Gothic, Renaissance, Baroque, Neoclassical, and more contemporary styles.

The Routes of Santiago de Compostela in France are also World Heritage sites in their own right as is the city of Santiago de Compostela and the Cathedral of Burgos.

Royal Monastery of Santa María de Guadalupe

The Monastery of Santa María de Guadalupe was declared World Cultural Heritage in 1993. It was included in the World Heritage list as an ensemble of religious architecture erected during four centuries and as symbolizing two historically important events: the expulsion of Muslim power from Spain and the discovery of America by Christopher Columbus, both in 1492. The Virgin of Guadalupe also became the symbol the Christianization of the New World (Advisory Body Evaluation 665 1993, pp. 56–57).

At the end of the thirteenth century, a shepherd claimed to have found the statue of the Virgin Maria beside the Guadalupe River, and a chapel was erected dedicated to Our Lady of Guadalupe. King Alfonso XI declared this chapel a Royal Sanctuary after winning the battle of the Salado River (1340) having invoked the help of "Santa Maria de Guadalupe." In 1389 the sanctuary, which by then had developed into an important pilgrim destiny, was declared a monastery and taken over by Hieronymite monks. It became the most important monastery in Spain. In 1835 it was dissolved but revived in 1908 by Franciscan monks (García 1993, pp. 12–27).

The monastic complex comprises the main church in Gothic style from the fourteenth and sixteenth centuries, the Baroque sacristy built between 1638 and 1647 with paintings from Zurbarán, the chapel of Santa Catalina from the fifteenth century, the Reliquaries Chapel from the end of the sixteenth century, the Baroque Chamber of the Virgin built between 1687 and 1696, the Mudéjar cloister built between 1389 and 1405, the Gothic cloister built between 1531 and 1533, and the New Church built between 1730 and 1735 (Advisory Body Evaluation 665 1993, pp. 54–55).

Historic Walled Town of Cuenca

The Historic Walled Town of Cuenca was declared World Cultural Heritage in 1996. It was included in the World Heritage list as an essentially intact example of a fortress town from the Middle Ages, with all its religious and secular buildings from the twelfth to the eighteenth century, which integrates perfectly into the rural and natural landscape (WHC.96/CONF.201/21 1996, p. 72).

Cuenca was established as a fortified town after the Muslim conquest of the area during the eighth century and as a provincial capital. In the twelfth century, it was conquered by Castile. From the fifteenth to the seventeenth centuries, it was one of the important textile- and livestock-producing cities in Spain, before its subsequent decline. Especially significant are the first Gothic cathedral of Spain, the so-called *Hanging Houses*, which are built on a cliff over the Huéscar River, and the fortifications. The World Heritage site extends over 23 ha (Historic Walled Town of Cuenca 2017).

La Lonja de la Seda de Valencia

The Lonja de la Seda in Valencia (the Silk Exchange) was declared World Cultural Heritage in 1996. It was included in the World Heritage list as an exceptional example of a secular building in Late Gothic style which bears witness to the power and wealth of a great mercantile city (WHC.96/CONF.201/21 1996, p. 72).

The *Lonja* was built between 1482 and 1533, during the Middle Ages and early modern times in one of the most important trading ports on the Mediterranean Sea. The *Lonja* became the commercial center of the city and housed also the institutions of the *Consolat de Mar* (commercial) and the *Taula de Canvis i Diposits* (banking) (Advisory Body Evaluation 782 1996, p. 88).

The *Lonja* has been built in Late Gothic style, the two most notable parts being the facades and interior of the *Sala de Contratació* (contracting hall) in Flamboyant Gothic and the *Cambra Dourada* (Gilded Chamber) with carved, gilded, and painted decoration (Advisory Body Evaluation 782 1996, p. 89).

Las Médulas

The human-made Las Médulas landscape in Galicia in northwestern Spain was declared World Cultural Heritage in 1997. It was included in the World Heritage list as an example of an ancient landscape

resulting from innovative Roman gold-mining technology (WHC.97/CONF.208/17 1997, p. 48).

The gold deposits of the region had been exploited on a small scale long before the Romans conquered the area in 19 BC. During the first century AD, the Romans started to exploit the deposits of the Las Médulas area on a large scale using very innovative though environmentally destructive engineering techniques, with hydraulic works with dams, channels, and road building, leaving behind the landscape and archaeological site we find today. The extraction of gold was stopped at the beginning of the third century (Advisory Body Evaluation 803 1997, pp. 103–104).

The World Heritage site expands over 2,208 ha (Las Médulas 2017)

The technique used consisted in collecting water in large reservoirs, which was led by a system of well-built gravity canals to the mines. Galleries were cut into the rock above the gold-bearing strata. After opening the dams, great quantities of water flowed into the galleries, which were closed at their ends, pressure built up and caused the rock to explode and to be washed away, forming enormous areas of tailings. Afterward the galleries in the gold-bearing strata were flooded in the same way, but then the auriferous material led through canals where the gold would separate under gravity from the rest of the material and sink to be extracted at the end (Advisory Body Evaluation 803 1997, p. 104).

Palau de la Música Catalana and Hospital de Sant Pau, Barcelona

The Palau de la Música Catalana and the Hospital de Sant Pau were declared World Cultural Heritage in 1997. They are the outstanding works of the Catalan architect Lluís Domènech i Montaner. They were inscribed in the World Heritage list as masterpieces of the imaginative and exuberant Art Nouveau from the early twentieth century (WHC.97/CONF.208/17 1997, p. 48).

The Palau de la Música and the Hospital de Sant Pau are the most outstanding examples of the *Modernisme* (Catalan Modernist Style or Art Nouveau) which tries to bring tradition and modernity together in an artistic style (Advisory Body Evaluation 804 1997, p. 106).

The Palau de la Música was erected between 1905 and 1908 and is a very good example of an early steel skeleton with curtain walls mainly of glass and large open spaces inside. The building is exuberantly decorated with European musical traditions as motifs.

The Hospital de Sant Pau was started by Lluís Domènech i Montaner in 1901 and finished by his son, Pere Domènech i Roura, in 1930 following the plans of his father. Like the Palau de la Música, the Hospital de Sant Pau brings functionality and the decorative arts together. From the beginning the idea was not simply to decorate the buildings with glazed tiles, bright-colored paintings, sculptures, and stained-glass windows but to use decorative beauty, and green spaces, to help the recovery of the sick. With its 14 ha, it is the largest hospital complex in the world in the Modernist style. It consists of 19 independent buildings which are connected through underground galleries with a total length of nearly 2 km (Advisory Body Evaluation 804 1997, pp. 106–107; L'Hospital 2017).

Pyrénées: Mont Perdu

The site of Pyrénées – Mont Perdu – was declared World Heritage in 1997 as a mixed site: cultural and natural. In 1999 the site was extended. It is also a site which includes two state parties: France and Spain. It was included in the World Heritage list as a cultural landscape with an outstanding beauty and an ancient socioeconomic structure of the mountains which, today, is rare in Europe (WHC.97/CONF.208/17 1997, p. 39).

The Mont Perdu massif is located in the Pyrénées on the French-Spanish border. On its southern side, it is characterized by deeply incised canyons and on its northern side by cirque walls. There are remains of human activity from the Upper Paleolithic (40,000–10,000 BC): the Añisclo and Escuain caves, the stone circles at Gavarnie, and the dolmen at Tella. The first documented settlements are from the Middle Ages and still perceptible in tracks and roads, bridges, houses, and hospices. Seven villages with their pastures and meadows still practice today an economic system based on the transhumance of sheep, cows, and horses, which was

once widespread in Europe but has nearly totally disappeared today. This system has brought the communities on both sides of the mountains and border closer to each other than to the communities in the plains north and south of the mountains. The site encompasses 30,639 ha (Advisory Body Evaluation 773 1997, p. 1).

San Millán Yuso and Suso Monasteries

The two monasteries of San Millán de Suso and San Millán de Yuso in North Central Spain were declared World Cultural Heritage site in 1997. They were included in the World Heritage list as a testimony to the Christian monasticism existing from the sixth century until today. Furthermore they are seen as the birthplace of the modern written and spoken Spanish language (WHC.97/CONF.208/17 1997, p. 48).

In the Suso Monastery, we find traces of monastic buildings from the sixth century (Visigothic), while the main parts are built in Romanesque and Mozarabic style. Not far away from the Suso Monastery, the Yuso Monastery was inaugurated in 1067. Until the twelfth century, both monasteries existed independently side by side, since then we find only one community of Benedictine monks. The Yuso Monastery is mainly in Renaissance and Baroque style. The site covers 19 ha (Advisory Body Evaluation 805 1997, p. 110; San Millán Yuso and Suso Monasteries 2017).

Although there is no proof that these monasteries have been literally the birthplace of the Spanish language, it is the place where the oldest known written document with Castilian parts has been produced: the Codex Aemilianensis 60 from the ninth and tenth centuries. The text is in Latin but with annotations in Castilian and Basque (Advisory Body Evaluation 805 1997, p. 110).

Prehistoric Rock Art Sites in the Côa Valley and Siega Verde

The prehistoric rock art site in the Côa Valley in Portugal was declared World Cultural Heritage in 1997. In 2010 the site was extended to the Siega Verde site in Spain. Both sites were included in the World Heritage list as unique examples of rock engravings from the Upper Paleolithic to the final Magdalenian/Epipaleolithic (22,000–8,000 BC), and as first manifestations of human symbolic creation from the beginning of human cultural development, and as an unrivalled source for understanding Paleolithic art, which helps to understand the social, economic, and spiritual life of our early ancestors (WHC-10/34.COM/20 2010, pp. 229–230).

The engravings on both locations were made on the rocky cliffs of the banks of the Águeda and Côa Rivers over several thousands of years starting on the Spanish site around 21,000 BC and ending between 10,000 and 7,000 BC. The techniques used were incisions or pecking. On the Spanish site, we find 645 rock surfaces engraved with subjects including animal groups like horses, bovids, and cervids, though sometimes we find human or geometric forms (Advisory Body Evaluation 866bis 2010, p. 324).

Rock Art of the Mediterranean Basin on the Iberian Peninsula

The prehistoric rock art sites on the seaboard or far inland of the Spanish Mediterranean basin were declared World Cultural Heritage in 1998. They were inscribed into the World Heritage list as the largest group of rock art sites in Europe, which help to form a picture of human life in late prehistoric times (WHC.98/CONF.203/18 1998, p. 31).

A total of 758 rock art sites in rock shelters and open rock surfaces stretches over more than 1,000 km from Catalonia in the North to Andalusia in the south. The painted subjects are naturalistic animal figures, stylized human figures, and dynamic hunting, combat, and social scenes in red, black, yellow, and white. The paintings, especially those with the hunting, combat, and social scenes, give valuable information about different aspects of human life and activity in prehistoric times: hunting, trapping, tracking of wounded animals, harvesting, and beekeeping, a first evidence of organized military confrontations and executions, social differences, clothes, personal adornments, funeral rites and other rituals, healers, divinities, and fantastic figures that combine human and animal characteristics. The dating of the paintings is still debated as the subject matters include typical scenes from the lives of hunter-gatherers of the Epipaleolithic (10,000–5,000 BC)

but also the first forms of Neolithic sedentary, agricultural life from the period after (until 3,500 BC) (Advisory Body Evaluation 874 1998, pp. 51–52; Rock Art 2017).

University and Historic Precinct of Alcalá de Henares

The University and Historic Precinct of Alcalá de Henares were declared World Cultural Heritage in 1998. They were included in the World Heritage list as the first city to be established solely as the seat of a university, which became the model for other such places in Europe and America, as the first place where it was intended to realize the concept of the ideal city, *The City of God* (*Civitas Dei*), and because of its contribution to intellectual development in the field of linguistics (e.g., definition of the Spanish language) and Miguel de Cervantes Saavedra (*Don Quixote*) who was born there (WHC.98/CONF.203/18 1998, p. 31).

Cardinal Francisco Jimenéz de Cisneros established the university in the city of Alcalá de Henares in 1499 with the project to build a university city dedicated entirely to the task of learning and teaching following the humanistic idea of the *Civitas Dei*. The old medieval town of Alcalá de Henares was during the following decades expanded to the east adding new institutions of learning, streets, sewer systems, houses for professors and students, printing workshops, and other services. In the sixteenth century, the university had more than 12,000 students, but this number declined during the seventeenth century in favor of Madrid, and in 1836 the university was closed. In 1977 a new university was inaugurated using the buildings of the old one.

The most outstanding buildings are the *Universidad y Colegio Mayor de San Ildefonso*, built between 1537 and 1553 in Plateresque style; the *Iglesia Magistral*, finished in 1515 in Gothic style; the Archbishop's Palace with its central part built during the sixteenth century in Plateresque style; the *Convento de San Bernardo* from the beginning of the seventeenth century in Baroque style; the *Patio Trilingüe* built between 1564 and 1570; *Paraninfo Universitario* built between 1516 and 1520 in Mudéjar and Plateresque style; and *the Iglesia de Jesuitas* built between 1602 and 1620 in Baroque style (Advisory Body Evaluation 876 1998, pp. 56–57).

The whole World Heritage site comprises 79 ha (University 2015).

Ibiza, Biodiversity and Culture

The site of Ibiza was declared World Heritage in 1999 as a mixed site. The natural is an example for the interaction between marine and coastal ecosystems. It was included as a cultural site in the World Heritage list because its intact sixteenth-century fortifications are valued as a testimony and example to the military architecture, the engineering, and the aesthetics of the Renaissance. Furthermore it was included as an exceptional evidence of urbanization and life in the Phoenician colonies because of the Phoenician ruins of Sa Caleta and the Phoenician-Punic cemetery of Puig des Molins (WHC.99/CONF.209/22 1999, p. 11).

The town of Ibiza, on the Spanish island of Ibiza, was founded as *Ebysos* in 654 BC by the Carthaginians. Local economy has been until the mid-twentieth century based on salt, wool, and figs. The island and its fortified harbor had been an important strategic location in the Western Mediterranean used by Romans, Arabs, Catalans, and Spaniards. This is why under Philip II of Spain in 1584–1585 new Renaissance fortifications were erected which were to become a model for many sites in the New World. The World Heritage site comprises 11,231 ha (Advisory Body Evaluation 417rev 1999, pp. 11–12; (Ibiza 2017).

San Cristóbal de La Laguna

The town of San Cristóbal de La Laguna on the Spanish Canary Islands was declared World Cultural Heritage in 1999. It was included in the World Heritage list as the first non-fortified Spanish colonial town and model for many newly established towns in America (WHC.99/CONF.209/22 1999, p. 17).

San Cristóbal de La Laguna was founded in 1497 on the Canary Island of Tenerife. The Canary Islands had been the first Spanish overseas territory conquered between 1402 and 1495 by the Kingdom of Castile which was the founding

nucleus of the Spanish Empire. It was the first territory on the way to the New World.

The first settlement was erected without any town-planning concept: today's Upper Town. This changed in 1502 when a plan following the plan for Imola in Italy by Leonardo da Vinci was implanted. Separated from the Upper Town, the Lower Town had a grid plan where major streets linked the open public spaces, with smaller streets superimposed in between. The new town attracted many new dwellers, and new public buildings, religious edifications, and private houses were erected. The town became the political, religious, and economic center of the islands until at the end of eighteenth century this position was lost. The outstanding position of San Cristóbal becomes explicit in its rich monumental heritage from the sixteenth to the eighteenth centuries (Advisory Body Evaluation 929 1999, pp. 105–106).

The site comprises 60 ha (San Cristóbal 2017).

Archaeological Ensemble of Tárraco

The Archaeological Ensemble of Tárraco (the modern city of Tarragona in Catalonia/Spain) was declared World Cultural Heritage in 2000. It was incorporated into the World Heritage list as an exceptional testimony and example of an important period in Mediterranean antiquity and as a model of Roman urban planning for provincial capitals (WHC.00/CONF.204/21 2000, p. 48).

There was a settlement on the site of Tárraco before the Roman conquest. In 218 BC the Roman Proconsul Scipio Africanus fortified this site, and it developed into the base of Roman power and culture on the Iberian Peninsula. Under Augustus it became the capital of the province of *Hispania Citerior* (*Tarraconensis*) and central place of the Imperial cult in Iberia. Until the end of the Roman rule, it was administratively, commercially, and culturally one of the most important cities on the Iberian Peninsula.

Many of the Roman remains are beneath existing buildings. The Roman buildings or parts of them preserved over the last two millennia or revealed in excavations are the ramparts mainly from the second century BC; the imperial cult enclosure built in the first century; the provincial forum with the *praetorium*; the circus built in the first century AD; the colonial forum from the first century BC; the theater from the beginning of the first century AD; the amphitheater with space for 14,000 people, built at the beginning of the second century AD, abandoned in the mid-fourth century, and reused as a location first of a Visigothic and then Romanesque church; and the Paleochristian cemetery from the third century with more than 2,000 tombs. Further away from the city itself, we find a part of the aqueduct which brought water to the Roman colony, the Tower of the Scipios, a funerary monument from the first half of the first century AD; the Médol Quarry from where many of the material for the constructions in Tárraco came; the Centcelles Villa-Mausoleum which had been a *villa rustica* established during the second century and changed into a mausoleum during the fourth century; the Dels Munts Villa, a luxurious suburban villa first constructed at the start of the first century AD and enhanced during the third century AD; and finally the Triumphal Arch of Berá, probably a territorial marker from around 13 BC (Advisory Body Evaluation 875rev 2000, pp. 141–143).

Archaeological Site of Atapuerca

The Archaeological Site of Atapuerca was declared World Cultural Heritage in 2000. It was included in the World Heritage list as the earliest and most abundant evidence of humankind in Europe whose fossil remains give extraordinary information about the physical nature and way of life of the earliest human communities there (WHC.00/CONF.204/21 2000, p. 49).

The site of Atapuerca near the city of Burgos encompasses deposits of human fossils from the Pleistocene (Trinchera del Ferrocarril, including the Gran Dolina, the Galería-Tres Simas, and the Sima del Elefante, and the Cueva Mayor including the Sima de los Huesos) with fossils from 1,200,000 BP onward and from the Holocene (El Portalón de Cueva Mayor, Galería del Sílex, Cueva del Silo, and Cueva del Mirador) with fossils from 10,000 BP until the Common Era. These human fossils are accompanied by animal fossils and stone tools. Besides, there have been made other archaeological findings in Atapuerca from the Paleolithic, Neolithic,

Bronze Age, and Iron Age. The site covers a total of 284 ha (Advisory Body Evaluation 989 2000, pp. 181–182; Bermudez de Castro et al. 1997, pp. 1392–1395; Archaeological Site of Atapuerca 2013).

In 1997 various archaeologists and anthropologists claimed that the human fossils they found belonged to a new, separate human species; they named *Homo antecessor*. Since then it has been an ongoing debate on the link between this and the other human species (the last common ancestor of the *Homo neanderthalensis* and the *Homo sapiens*, the link between the *Homo ergaster/erectus* and the *Homo heidelbergensis*, a separate species that evolved from *Homo ergaster/erectus*, actually not a separate species but just a *Homo heidelbergensis*) (Bermudez de Castro et al. 1997, pp. 1392–1395; (Klein 2013, pp. 107–110; Sarmiento et al. 2007, pp. 185–221).

Catalan Romanesque Churches of the Vall de Boí

The Catalan Romanesque churches of the Vall de Boí, high in the Catalan part of the Pyrenees mountains, were declared World Cultural Heritage in 2000. They were inscribed into the World Heritage list as testimony to the important cultural interchange in medieval Europe expressed in the Romanesque architecture of these churches and as a consistent example of Romanesque art in a nearly untouched rural setting (WHC.00/CONF.204/21 2000, p. 48).

The Vall de Boí is a narrow valley surrounded by mountains with typical small Pyrenean villages embedded in enclosed fields, of which each has its own small Romanesque church. The ensemble consists of nine churches: Sant Feliú at Barruera, Sant Joan at Boí, Santa Maria, and Sant Climent (the largest, best preserved and architecturally best example of all) at Taüll, the Church of the Assumption at Coll, Santa Maria at Cardet, the Church of the Nativity and the Hermitage of Sant Quirç at Durro, and Santa Eulàlia at Erill la Vall. The Lombard Romanesque style and interior artworks make Sant Climent at Taüll the symbol of Catalan Romanesque architecture (Advisory Body Evaluation 988 2000, pp. 176–177).

Built during the eleventh and twelfth centuries, the churches are all in the Lombard Romanesque style brought to the valley by itinerant monks and merchants and adapted to the mountain environment developing its own strong and expressive personality. The entrance of the Lombard Romanesque style into this region (Catalonia) of the Iberian Peninsula and its later expansion to other parts of it shows how Catalonia with its nominal Frankish overlords from the north of the Pyrenees was better connected to the rest of Christian Europe and to cultural influences from Italy than the other Christian kingdoms of the Iberian Peninsula (Advisory Body Evaluation 988 2000, pp. 175–176).

Most of the original mural art works were moved for conservation reasons to Barcelona during the 1920s, where they are exhibited in the Museu Nacional d'Art de Catalunya (MNAC).

Palmeral of Elche

The Palmeral (palm grove) of Elche was declared World Cultural Heritage in 2000. It was incorporated into the World Heritage list as an outstanding example of the transference of a characteristic landscape from one culture and continent to another, from North Africa to Europe, and because of its irrigation system (WHC.00/CONF.204/21 2000, p. 48).

The palm groves of Elche in the south of the Spanish region of Valencia were planned and implanted under Muslim rule from the eighth century AD. Date palms had existed in the area long before, but palm groves as oasis, typical Northern African and Arab agricultural production system for arid regions based on sophisticated irrigation systems, were introduced at this moment. There are in total 67 palm groves which together cover 144 ha (Advisory Body Evaluation 930 2000, pp. 137–138).

Roman Walls of Lugo

The Roman Walls of Lugo, a town in the Spanish region of Galicia, were declared World Cultural Heritage in 2000. They were included in the World Heritage list as the best intact example of a late Roman military structure (WHC.00/CONF.204/21 2000, p. 48).

The Romans founded the town of Lugo (*Lucus Augusti*) in 15/13 BC after the military occupation of the area. The town was laid out following Roman town planning principles. This first settlement had no special fortifications but after the first invasions of Roman territory by Germanic tribes many cities of the Empire received fortifications, which was also the case of Lugo. The walls were built between 263 and 276 AD (Advisory Body Evaluation 987 2000, p. 134).

The walls of Lugo are the most complete and original Roman military fortifications to be found today. They have a length of 2,117 m and enclose an area of 34 ha. They are 4.2 m thick, in some places up to 7 m; their height lies between 8 and 12 m. There are 46 towers intact and the remains of another 39, and 10 gates, from which 5 are original Roman. There are still internal stairways and internal and external walkways (Advisory Body Evaluation 987 2000, p. 135).

Aranjuez Cultural Landscape

The Aranjuez Cultural Landscape in Central Spain was declared World Cultural Heritage in 2001. It was incorporated into the World Heritage list as a cultural landscape created out of different cultural influences, which was a landmark in landscape design and became influential in further developments (WHC.01/CONF.208/24 2001, p. 46).

Aranjuez, placed on the Tagus and Jarama rivers, was a Royal Site from the fifteenth century, but it was Philip II who, in the sixteenth century, built the first palace and planted the first ornamental and vegetable gardens with plants from all over his worldwide empire following practices (hydraulic engineering) from Central Europe and Italy. During the seventeenth century, Aranjuez became a retreat for the royal court for pageantry and hunting. In the eighteenth century, a newly planned town was added to the palace, and under Charles III it was made an experimental ground for physiocratic, agricultural, scientific, and social ideas (Advisory Body Evaluation 1044 2001, p. 129).

The site of Aranjuez comprises different zones: the Palace with the Island Garden (ornamental, geometric or irregular), the Great Historic Garden (vegetable gardens, tree-lined avenues and groves, with irrigation systems), the planned town from the eighteenth century, and the Prince's Garden (designed in different periods). Together, the different zones conceptually create different landscapes which altogether make up the cultural landscape of Aranjuez: a water landscape with rivers, ponds, dams, ditches, and fountains; an agricultural landscape with vegetable gardens, orchards, plant nurseries, and stock-breeding farms; a beautiful landscape for leisure designed in Renaissance style with Arab touches, in Baroque style, in French Classicism style, in English style, or in nineteenth-century bourgeois style; an ordered geometrical landscape with the ornamental geometric gardens, the irrigation systems, and agricultural gardening plots; the geometry of the streets and squares; and a constructed landscape with the palace, the planned town, the roads, the agricultural buildings, and the irrigation systems. The site has an extension of 2,048 ha (Advisory Body Evaluation 1044 2001, pp. 130–131; Aranjuez Cultural Landscape 2017).

Renaissance Monumental Ensembles of Úbeda and Baeza

The Renaissance Monumental Ensembles of Úbeda and Baeza in the Spanish region of Andalusia were declared World Cultural Heritage in 2003. They were included in the World Heritage list as outstanding examples of architecture and town planning during the Renaissance and instrumental in the introduction of Renaissance ideas to Spain and their diffusion to America (WHC.03/27.COM/24 2003, p. 121).

The two towns of Úbeda and Baeza lie only 9 km from each other. Both had been smaller settlements until the conquest by the Muslims in the eighth century. From there they develop into more important fortress towns following the building pattern of Islamic Northern Africa and the Middle East. In the thirteenth century, the towns were conquered by Christian Castile but stayed with their main function as fortress towns. After the fall of the last Muslim stronghold on the Iberian Peninsula, Granada, in 1492, they lost this function, but they underwent an important economic growth

during the sixteenth century, putting the latifundist aristocracy and the church in the position to renovate and embellish them with new palaces, churches, and other buildings, even if the urban layout remains until today essentially Islamic (Advisory Body Evaluation 522rev 2003, pp. 153–154).

The most important buildings of the ensembles are in Úbeda, the Palace of Francisco de los Cobos (1531), the funerary chapel of El Salvador del Mundo (1532–1553), the Palace of Vázquez de Molina (1546), the Hospital Honrados Viejos (1548), the Palace of the Déan Ortega (1550), the Pósito (1558), the Palace of the Marqués de Mancera (1580–1600), the Cárcel del Obispo (late sixteenth century), and the Church of Santa María (thirteenth to nineteenth centuries), and in Baeza the Cathedral (1570s), the Casas Consistoriales Altas (1511–1526), the Fountain of Santa María (1564), the Seminary of St. Philip Neri (1598–1660), the Jabalquinto Palace (late fifteenth century), the Church of Santa Cruz (thirteenth century), and the University (second half of the sixteenth century) (Advisory Body Evaluation 522rev 2003, p. 153).

The site covers in total 9 ha (WHC.03/27.COM/24 2003, p. 121).

Vizcaya Bridge

The Vizcaya Bridge near the industrial Basque city of Bilbao was declared World Cultural Heritage in 2006. It was incorporated into the World Heritage list as an example of technical creativity with a satisfactory relationship between form and function, to create a hanging transporter mechanism that influenced other similar systems in the world (WHC.06/30.COM/19 2006, p. 154).

The Vizcaya Bridge is today a symbol of the Industrial Revolution. Built between 1887 and 1893, it is 45 m high and spans 160 m. It brings together nineteenth-century ironworking know-how with the at this moment new technologies of lightweight twisted steel ropes. It was the first bridge to transport people and goods in a hanging gondola above passing ships. It made it possible to build a bridge for communication between the two banks of the river without obstructing the ships or the need for long ramps even if the land was flat. It is still in use today (Advisory Body Evaluation 1217 2006, pp. 120–121).

Tower of Hercules

The Tower of Hercules, a lighthouse on the Spanish Galician coast at La Coruña, was declared World Cultural Heritage in 2009. It was included in the World Heritage list as a testimony to lighthouses from antiquity and to the continuity of the Atlantic shipping route since Roman times (WHC.09/33.COM/20 2009, p. 206).

The Tower of Hercules, originally called *Farum Brigantium*, was probably built at the end of the first century AD to mark the entrance to La Coruña's harbor. It is the only preserved Roman lighthouse still in use today. Over the centuries it has been renovated several times, the most important adaption coming in the eighteenth century. The Roman section measures 14 m^2 by 34 m high, the 21 m on the top corresponding to later renovations (Advisory Body Evaluation 1312 2009, pp. 168–169).

Cultural Landscape of the Serra de Tramuntana

The Cultural Landscape of the Serra de Tramuntana on the island of Mallorca was declared World Cultural Heritage in 2011. It was included in the World Heritage list as an exceptional cultural landscape created by the introduction of complex Arab irrigation systems, to make orchards and vegetable gardening possible on an island with many droughts, and the later expansion of the terraced and irrigation systems (including a drainage system which avoids erosion of the little soil available) to the hillsides by the Christian conquerors who introduced a feudal model. It developed a landscape characterized by rocky areas, strips of woodland, hillside terraces of olive trees, terraces with other crops, grazing land, fields for reaping, vineyards or different nonirrigated fruit crops, bigger estate houses, long walls enclosing estates, cobbled roads, towns and villages with an urban design of irregular little streets with steps and cul-de-sacs, complex water supply systems, public washing places, orchards, mills, and well-type water tanks amid stone houses, altogether in a Mediterranean

drystone architectural style. The site covers an area of 30,745 ha (WHC-11/35.COM/20 2011, pp. 223–224; Cultural Landscape 2017).

Heritage of Mercury: Almadén and Idrija

These are actually two sites (one in Central Southern Spain, one in Slovenia) which were declared World Cultural Heritage site as one under the name of *Heritage of Mercury: Almadén and Idrija* in 2012. They were included in the World Heritage list as the heritage left by the extraction of mercury, which was undertaken in only a few mines worldwide of which Almadén and Idrija were the largest. Since the Renaissance the importance of mercury had increased strongly because of its role in the extraction of gold and silver, mainly in America (WHC-12/36.COM/19 2012, pp. 205–206).

On the Spanish site of Almadén mercury had been extracted since ancient times. It became of very high importance during the sixteenth century with the conquest of Mexico and Peru by Spain because of the amounts of gold and silver to be extracted there. The mercury was shipped through the ports of Seville and Cadiz to the New World but also other European mining areas. The mines in Almadén closed in 2002/2004. It has been estimated that Almadén has provided during the last 2000 years about one third of the world's mercury (Advisory Body Evaluation 1313rev 2012, pp. 341–342).

The site of Almadén comprises the essential elements of mercury mining and the associated mining town: on the extraction site itself the mines with shafts, galleries, access and transport tunnels, mercury stores, furnaces from the seventeenth and eighteenth centuries, administrative and social buildings, in the mining town the Retamar Castle, the Chapel of San Miguel, the Mining Academy building, the superintendent's house, the Inquisitor's House, the San Sebastian el Nuevo church, the Carlos IV and Carros gates, the Miners' Hospital, the forced labour gaol and other dwellings. The Almadén site covers a total of 50 ha (Advisory Body Evaluation 1313rev 2012, p. 340; Heritage of Mercury 2017).

Antequera Dolmens Site

The Antequera Dolmens Site was declared World Cultural Heritage in 2016. It was incorporated into the World Heritage list as one of the most important engineering and architectural works of European Prehistory and an example of European Megalithism. The dimensions of the stone blocks employed using rudimentary technology, and the characteristics of the megaliths, are representative of the two great Iberian megalithic traditions (lintelled architecture in the cases of Menga and Viera and the architecture of El Romeral's false cupola ceiling) and have a special relation to the surrounding landscape of Antequera (the monuments are buried beneath earth tumuli, and two megaliths are oriented toward the natural landmarks of La Peña de los Enamorados and El Torcal). Furthermore, the megaliths in their natural context help to understand funerary and ritual practices of highly organized Neolithic and Bronze Age societies (WHC/16/40.COM/19 2016, p. 224).

The Antequera Dolmens Site comprises three human-made megalithic tombs (the dolmens of Menga and Viera and the tholos of El Romeral) and two natural landmarks (the mountain of La Peña de los Enamorados and the Sierra de El Torcal). All three tombs have still their tumulus. The Menga and the Viera dolmens are passage tombs with lintelled roofs, while the tholos of El Romeral is a corbel dome tomb with a false cupola. Menga consists of a mound (tumulus) of about 50 m in diameter and a megalithic gallery 27.5 m long and up to 6 m wide and a height rising from 2.7 to 3.5 m. It is oriented to the mountain of La Peña de los Enamorados where we find similar prehistoric symbolic art as in the dolmen itself. Viera consists of a mound of about 50 m in diameter with a long corridor which leads to a chamber with graphic and sculptural elements. The corridor and chamber together are 19 m long and 1.3 m wide with a height of about 2 m. El Romeral consists of a 26 m long and 1.5 m wide passage which leads to a circular chamber with a diameter of 5.2 m at its base and a vaulted ceiling with a height of 4 m. El Romeral faces to the highest point of the Sierra de El Torcal. La Peña de los Enamordos is a

mountain which since ever has been of high importance because of its location and anthropomorphic shape. The mountain range of El Torcal has various caves with archaeological sites from the Neolithic period and the Copper Age. It has been estimated that the Menga and Viera dolmens were erected during the fourth millennium BC, while the tholos of El Romeral in the period between 3,300 and 2,200 BC. The archaeological findings from La Peña de los Enamorados and la Sierra de El Torcal are probably from the same periods. The site covers a total of 2,446 ha (Advisory Body Evaluation 1501 2016, pp. 165–167).

Spatial Analysis in Field Archaeology

Bisserka Gaydarska
Department of Archaeology, Durham University, Durham, UK

Introduction and Definition

Spatial analysis deals with the use of space in the past. Such analyses are performed at two main scales: (a) *intra-site level* (some archaeologists argue for further differentiation within a site, defining micro and semimicro levels) and (b) *inter-site* or landscape level. Both analyses are concerned with finding patterns of distribution, whether of finds and features (usually at site level) or of sites and monuments. Spatial analysis at both site and inter-site level may also contribute to the elucidation of *sequence*. While the employment of some methods at both levels is broadly similar – e.g., *GIS*-based mapping or various statistical analyses, others are unique for each level. For example, GPR is more suitable for the establishment of intra-site patterns, while digital terrain modeling is more cost-effective on a landscape level. The number of methods and techniques used in spatial analyses is ever-growing and diversifying.

Key Issues

On Site (Intra-site)

On site, the plotting of artifacts and features allow the identification of certain activity areas (marked by objects), sleeping areas (blank spaces in a building), community areas (open spaces in a settlement), and so on. The mapping of finds may also indicate intrusions that are natural (the course of a stream) or anthropogenic (the line of a ditch) that are otherwise hard to see. Most often the analyses are performed after excavation and fieldwork is finished, which is why proper recording of locations during the investigations is crucial (see the entry on ▶ Recording in Archaeology in this encyclopedia). Analysis of the context records and an understanding of taphonomy and deposition (see also the entry on ▶ Site Formation Processes in this encyclopedia) is key for the correct understanding of, e.g., whether matching fragments of artifacts found in different contexts alludes to contemporaneity of the features (Kobyliński and Moszczyński 1992) or to the social practice of curation (Garrow et al. 2005). The relative size and disposition of structures and the routes between them are used to infer the relative importance (hierarchy) of buildings and the social routines practiced within a settlement.

At a smaller scale, *access analysis* explores the use of space by mapping the relative ease with which rooms may be approached within a house, allowing archaeologists to propose the location of high-ranking or special users. An eloquent example of access analysis was used to study social inequality on Bulgarian tells (Chapman 1990). Four more or less fully excavated tells (Ovcharovo, Targovishte, Radingrad, Poljanica) served as the basis for an analysis of the development of social space throughout their use (Fig. 1). The settlement maps showed the houses, the

S

Spatial Analysis in Field Archaeology, Fig. 1 Access levels of Bulgarian tells showing number of rooms and complexity of house organization (**a**) Targovishte and Radingrad; (**b**) Poljanitsa

number of rooms within them, and access to each room from the main entrance. At Targovishte and Radingrad (Fig. 1a), one or two rooms were accessible from the entrance and two or three further rooms reached in succession with minimal choice. By contrast at Ovcharovo and Poljanica (Fig. 1b), houses eventually contained up to 11 rooms with multiple choice of access, a pattern that was held

to reveal to the successful reproduction of social inequality. The simpler access pattern at Targovishte and Radingrad was interpreted as being owed to a relatively unstratified community, and it was suggested that failure to find an adequate material way to contain social rivalry led to the relatively short lifetime of these two tells.

In the Landscape (Inter-site)

In one of the most commonly practiced types of landscape investigation, the documentation of surface finds can provide information about the intensity of discard and, thereby, infer occupation (see the entry on ▶ Surface Survey: Method and Strategies). The mapping of features registered by noninvasive techniques (such as *aerial archaeology* and *subsurface investigations*), supplemented by detailed archival research (including historical records), is also used to create a narrative picture of landscape habitation. In most modern studies, a combination of survey methods is applied. The spatial particularities of the mapped distribution of features and artifacts in a landscape usually provide the basis for studies of settlement patterns; subsistence strategies; political, military, and ideological utilization; and reorganization of the landscape. The recognition of time depth is important in a landscape, as it is in an excavated site. The idea of a *palimpsest* (Aston and Rowley 1974) acknowledges that landscapes are "layered" as century follows century, giving so-called diachronic patterns. Thus, the establishment of changes over time by interrogating the evidence for erased episodes of human occupation, or identification of multiple phases of occupation, is a major task assisted by spatial analysis.

Early examples of spatial analysis at the landscape level generated maps with dots, representing sites and/or finds to which various analyses would be applied to improve the pattern using statistical packages such as *cluster analysis*. Such analyses set out to define not only the location of sites, but their relative importance (from their size or the quality of finds). The sites discovered are most often seen as settlements, but the same principles have been applied to cemeteries, burial mounds, and hill forts. *Central place theory* uses the size of settlements to construct dependent territories around them. The land was also routinely modeled by surveying the surface in three-dimensions and representing it in the form of *contours* or *hachures*.

More recent landscape studies have added to the power of spatial analysis by collecting different variables (for example, placenames, surface finds, settlement locations) and entering their coordinates into a computerized data base to make a series of digital maps. The stack of digital maps forms a *geographic information system* (GIS), which can be interrogated in a large number of ways in order to bring out spatial relationships between variables that are often unsuspected. The surface of the landscape itself can also be digitized using *LiDAR* imaging. The data collected from the air is used to generate a three-dimensional surface on the computer – a *digital terrain model* (DTM). Using graphics programs, the DTM can be viewed from different angles to offer a realistic vision of the landscape from different locations, in different periods (*hillshade models*). The same database can be used to generate models showing which parts of the land could be seen at other parts (*viewshed*). These new tools enable the ancient landscape, its settlement patterns, and the routes through it to be envisioned in considerable detail.

A recent project in the area of Homs in Northern Syria examining the distribution of settlement types was able to group them in revealing new combinations (Philip et al. 2011). Traditionally, the area of southwest Asia is perceived as a tell-dominated landscape and the southern marl-based part of the study area confirmed this observation. The northern study area, however, with its basalt environment seemed to have facilitated a different type of occupation. Single and clustered irregular and rectilinear units of different sizes, a stone enclosure, and many cairns mostly on slopes and ridges were mapped, revealing settlement clusters (Fig. 2). Functional and chronological differentiation was established between the grouped irregular and the grouped rectilinear structures, thus suggesting changing strategies of engagement with the landscape. Several "waves" of occupation/settling have been proposed, starting with the well-documented settlement expansion in

Spatial Analysis in Field Archaeology, Fig. 2 Structures in the North basalt study area of Homs, Syria, showing settlement clusters. (After Philip et al. 2011)

southern Syria during the Chalcolithic/Early Bronze Age and reoccurring in Roman and Byzantine periods, mostly associated with field systems – a pattern of land use that remained in place till modern times. The presence and mapping of thousands of hitherto overlooked cairns poses questions about the long-term landscape management of a stony environment that is intimately related to perpetuated social practices. The main result of this project is the demonstration of the diversification of the settlement patterns in Northern Syria in both space and time.

"Speculative Phase" of Archaeology

Debbie Challis
Petrie Museum of Egyptian Archaeology, University College London, London, UK

Introduction

The "Speculative Phase" is so named due to the nature of speculation that was involved in archaeology before it was formed as an academic discipline and established professional practice and training. Archaeology was speculative in every way: financial, individual, exploratory, for publicity, and to aggrandize nationhood. (Unfortunately financial speculation has never left the practice of collecting antiquities.) Many of these factors continued beyond the "Speculative Phase" and played a part before it. This entry covers the move from the collection of antiquities to archaeological excavation during the nineteenth century and also considers how archaeology was sponsored as well as the role of the "explorer-archaeologist." It argues that a shift to classificatory systems and detailed observation was informed by developments in the natural sciences. Further, it contends

that "informal imperialism" in Europe and North America was crucial to the development of archaeology in this phase and the role of archaeology in more formalized and military colonialism is examined in this regard.

From my perspective as a museum professional in Britain, I point to the legacy of the "Speculative Phase" in museums in debates around restitution as well as the display and repatriation of human remains. Related to these contentious issues is a greater curatorial comprehension of our own history, which is in turn presented to the wider public, and the re-emergence of the importance of amateurs and local societies in contemporary practice within British archaeology. There is a vast scope for future directions within this field and as a result this entry can only point to the importance of cross-disciplinary and international connections within scholarship, the continuing impact of "hero archaeology" and how this is related to the study of the role of the workforce in this period.

Definition

The "Speculative Phase" of archaeology is defined as covering the move toward excavation in the field and the construction of archaeology as a professional and academic discipline. It describes the shift away from amateur antiquarian organizations and "armchair" scholars to a more formalized involvement of institutions, such as museums, universities, and learned societies as well as the role of related individuals (Diaz-Andreu 2007). These institutions and individuals had an impact on archaeology across the world, but were based in Europe and North America during this period. Nationalist and imperial motivations also became more important in the collection of antiquities for display in museums (Trigger 1989).

The "Speculative Phase" of archaeology could encompass an extremely broad historical period and geographical area, extending from interest in the past in antiquity and ending with the formation of the study of archaeology as a discipline in universities in the early twentieth century. It has been defined previously in relation to American archaeology as lasting from 1492 to 1840 (Willey and Sabloff 1993). This definition begins with the removal of antiquities from monuments and rudimentary excavations in the early nineteenth century, but positions the main "Speculative Phase" as covering excavations from the 1840s to the 1870s. It gradually finishes in the 1880s and 1890s when archaeology was established as a subject in universities in Europe and North America. This period sees a gradual growth of more descriptive analysis and advanced methods in excavation.

A defining feature of the "Speculative Phase" is the intertwining of archaeology, the history of art and anthropology. These areas were formed as separate academic disciplines at around the same time. Classical archaeology and art history, for example, were closely interlinked due to the aesthetic writings of Winckelmann and Hegel. The Parthenon Sculptures, removed by Lord Elgin and his associates from Athens during the 1800s and bought for the British nation in 1816, were placed within "the territory of art through the deployment of concomitant discourses" through references to the marbles as "works" associated with the artist Pheidias (Whitehead 2009: 83). Archaeology was allied to anthropology in other areas, particularly in North American, Southeast Asian, and African archaeology (Christenson 1989).

Ethnography and archaeology were particularly intertwined with regard to prehistoric periods in all areas of archaeology. This intertwining can be seen clearly in the work of the anthropologist and archaeologist General Augustus Henry Lane Fox Pitt-Rivers. Pitt-Rivers' theory of the "evolution of culture," based on Darwin's *On the Origin of the Species* and ideas around "social Darwinism," was reliant on the idea of typology. Typologies were based on objects with similar functions being placed in a chronological sequence on the basis of design. An idea that was later crucial to the work of the archaeologist William Matthew Flinders Petrie. The Pitt Rivers Museum in Oxford still organizes Pitt-Rivers' collections and objects from across the world in these typologies. Pitt-Rivers also applied this idea to his

work in field archaeology on Paleolithic, and other, sites in England and Ireland.

Historical Background

Collections of classical sculpture had been made by wealthy patrons in Europe since the Renaissance (Haskell and Penny 1981). The "Speculative Phase" moves from armchair scholars to excavation and mapping of actual antiquities and sites in the field. An early example of this shift is the scientific expedition of artists, antiquarians and engineers, known as the "savants," who were sent to assist the army in the French military invasion of Egypt in 1798–1801. The savants also mapped archaeological sites, making accurate drawings and collected antiquities. Their observations and findings were published as the *Description de l'Égypte* between 1809 and 1820. The impact was as much on contemporary style and fashion as archaeological practice. However, the *Description* set an exceptional standard for recording investigations of ancient sites and monuments. Arguably, though, the more immediate influence of the French expedition was on the removal of antiquities from sites elsewhere, usually from the South or Eastern Mediterranean, for public display in national museums.

The removal of the sculptures from the Parthenon and other monuments on the Acropolis by the British peer Lord Elgin and his team in the early 1800s was accompanied by a less well-known collection of drawings and maps of the buildings on the Acropolis (Gallo 2009). The subsequent sale of the so-called Elgin Marbles marked a shift from a private collection of antiquities built up through auctions in Italy and elsewhere and the removal of objects either from a building in situ or excavated from the ground. The group of architects and antiquarians known as the Xenion Society excavated sculptures from the Temple of Aphaia in the Greek Island of Aegina and from the Temple of Apollo in Bassae in the Greek Peloponnese. They sold the antiquities at public auction: the Aegina sculptures to the Crown Prince of Bavaria in the first instance for display in his new museum the Glyptothek in 1812 and the Bassae sculptures to the British Commandant of the Ionian Islands for display in the British Museum in 1815. These rudimentary excavations and removals were speculative in a financial sense as well as in a theoretical one and were dictated by contemporary artistic taste for Greek sculpture. Nevertheless, they mark an important shift from collection to excavation, however rudimentary.

Travel and related literary observation was important in developing early archaeology. It was such literary speculation made by travellers around the mounds and ruins found in western parts of North America that gave rise to the myth of the "mound builders." This myth held that the "mounds" could not have been built by Native Americans but must have been erected by a "more civilized race" that had since migrated or disappeared (Willey and Sabloff 1993). This myth continued until late into the nineteenth century, despite surveying of the mounds by E.G. Squier and E.H. Davis in the 1840s, later published as *Ancient Monuments of the Mississippi Valley* in 1848. Squier and Davis' work had the support of the American Ethnological Society and was published by the newly formed Smithsonian Institution. This institutional support for the surveying and connection to a learned society was indicative of the move from an amateur to a more professional focus. The mound builder controversy was also typical of theories around migration and archaeology based on ideas of "racial" hierarchies and diffusionism that existed well beyond the "Speculative Phase."

Emphasis on successive development was supported by the use of classification systems. For example, the periodization of "prehistory" was put into three ages: the Stone Age, the Bronze Age, and the Iron Age by the Danish curator and archaeologist Christian Jürgensen Thomsen. Thomsen based these three ages on accounts from archaeological reports and typologies of different grave goods in the early 1800s. He equated these with different layers in the ground. Thomsen's "three ages" had a profound effect on the understanding of prehistory and typologies more generally; in fact, these ages are still reflected in the display of objects in the Pre-History Galleries of the National Museum of

Denmark in Copenhagen today. The publication of Thomsen's *Primeval Antiquities of Denmark* by J.J. Worsaae in 1849 meant that the "three ages" would have a major impact in the English speaking world (Stocking 1985: 72–73). The shift from speculative to systematic archaeology was also assisted by developments in the natural sciences such as Charles Lyell's *Principles of Geology* (1830–1833), which defined geology as "the science which investigates the successive changes that have taken place in the organic and inorganic kingdoms of nature." Lyell's *Principles* illustrated how fledgling disciplines with aspirations to scientific status could define themselves. The process of successive phases of geological development also influenced the idea of the "great chain of being" within art, anthropology, and archaeology. The "great chain of being," or "chain of art," defined civilizations in successive phases of excellence and merit, with the Greek art of fifth-century BCE Athens at the top.

Key Issues/Current Debates

One of the key issues in this period is national aggrandizement and the role of the state in funding international archaeological excavations characterized by the "informal imperialism" of northern European countries. The Eastern Mediterranean particularly documents the move toward large-scale excavation in the 1840s through the expeditions of Charles Texier in Turkey (1833) for the French Ministry of Culture, Charles Fellows in Lycia Turkey (1841–1843) for the British Museum, and Paul Emille Botta in Assyria (1842–1845) for the Louvre and Austen Henry Layard (1845–1851) for the British Museum. Although it should be noted that Britain and France had very different approaches toward funding and the role of the state in archaeological sponsorship. The French Ministry of Culture had a far more direct approach, while the British had a "public-private partnership" between individual "explorer-archaeologists," the British Museum and the Foreign Office (Hoock 2007) for which careful diplomacy was essential. The interest of German States in excavation and purchasing antiquities had already been illustrated by the sale of the Aegina sculptures in 1812. After German unification in 1871, the German Archaeological Institute and related national museums played a much larger role in competing for excavation permits at sites and antiquities well into the twentieth century. Similarly, the formation of societies and museums in the United States of America as well as increasing interest of the Ottomans in the ancient past of their own Empire meant that from the 1870s Britain and France no longer carved up the Eastern Mediterranean between themselves.

The nebulous role of diplomacy within "informal imperialism" was an important factor of the "Speculative Phase" of archaeology and has not been fully investigated. A good example of the connections between excavation, collecting for the nation and diplomacy is in the 1852 appointment of Charles Newton, a former assistant curator at the British Museum, as vice-consul in Lesvos, at that time part of the Ottoman Empire, with a remit to collect antiquities (Gunning 2009). Newton's appointment and subsequent excavations at the Mausoleum of Halicarnassus and surrounding area in 1856–1858 heralded a different approach to archaeological excavation (Fig. 1).

Newton created a team to excavate that was composed of professional engineers, artists, surveyors, and photographers, as well as local Turkish workers and British sailors from the Royal Navy. He made tentative steps in field excavation through mapping and photography, which was followed by Richard Popplewell Pullan's excavation at Priene in Turkey in the 1860s and his grid-mapping system (Fig. 2).

Newton took the credit for the discovery of the Mausoleum of Halicarnassus, a lost "wonder of the world," though it has since been proved that the engineer Robert Murdoch Smith located the site of the Mausoleum. This subsequent discovery damaged Newton's posthumous reputation but illustrates the importance of claiming credit for discoveries.

The "Indiana Jones" image of a charismatic heroic archaeologist was also formed during this "Speculative Phase." The display of these

"Speculative Phase" of Archaeology,

Fig. 2 "Great Stone Outer Face," from Newton and Pullan (1862), Plate VIII

antiquities in a museum, and usually in the national museum, led to public interest fuelled by media coverage as well as the lionizing of the archaeologists themselves (Stiebling 1994). Giovanni Battista Belzonni was an earlier example of a "showman archaeologist" and was literally a showman before travelling to Egypt in 1815 and collecting antiquities.

As noted above, a key emphasis in the "Speculative Phase" is on the archaeologist as

heroic explorer. Archaeologists in Britain in particular needed to campaign to get funding and public support for their excavations from government and museum bodies. Austen Henry Layard is probably the most high profile example of this kind of "explorer-archaeologist" and he energetically publicized his discoveries in Assyria through publications of travel/archaeological books, lecture tours, newspapers and magazines (Fig. 3).

Layard tapped into public interest in biblical archaeology to gain support from an apathetic establishment at the British Museum. Although these budding archaeologists made claims in advancing scientific methods, and in many cases did so, the hasty practice of Heinrich Schliemann

"Speculative Phase" of Archaeology, Fig. 3 An example of magazine interest. "Our artist sketching the entrance gate of the Acropolis at Mycenae," from Illustrated London News (1877)

at Troy and the fabricated evidence of Louis Palma di Cesnola in Cyprus undermined their importance in the role of professionalizing archaeology (Challis 2008). Explorer-archaeologists continued in importance after archaeology had been established as a discipline, such as Hiram Bingham III searching for Machu Picchu in Peru in 1911. Archaeologists who also had professional positions in the late nineteenth and early twentieth century, such as William Matthew Flinders Petrie, Arthur Evans or Howard Carter, are still individually associated with particular sites or areas of archaeology (Fig. 4).

The combination of creating teams of people with different areas of expertise as illustrated by Newton's excavations in Halicarnassus combined with public interest in archaeological excavation led to the "big digs" of archaeology, which were "generally centered on a major site of great historical and cultural importance (Dyson 2006: 124)." The term "big scholarship" more properly describes the Olympia excavation carried out under the direction of Ernest Curtius by the German Archaeological Institute between 1875 and 1881 (Marchand 1996). The excavations at Olympia pointed to the future of classical archaeology with an excavation team of around 500 workers with different areas of expertise. At the same time, the charismatic if controversial Heinrich Schliemann was carrying out far less exacting excavations at the site of Hisarlik (Troy) in Turkey (1870–1873, 1878–1879, 1882–1883, and 1888–1890) and then Mycenae in Greece (1876–1878). These were "big digs" in every sense: big in scope, ambition, publicity, ego, and controversy (Traill 1995). Yet even Schliemann's last excavation at Troy was informed by new methodologies in archaeological stratigraphy.

The German Archaeological Institute is an example of the growing professionalization of learned societies and their part in establishing the discipline of archaeology. Formed out of the "Instituto di corrispondenza archeologica," founded in Rome in 1829, by 1871, it was a Prussian state institute and then in 1874 it became an imperial institute and a linked department, or "school," was also opened in Athens. The French Academy of Science had been established in the seventeenth century but had become particularly important in disseminating archaeological study and excavation reports after the French expedition to Egypt. It was the "German model" that guided efforts in Britain and America in establishing archaeology as a scientific profession (Kehoe and Emmerions 1999). The British Archaeological Association was formed in 1844 and the British Association for the Advancement of Science, founded in 1831, and its yearly conference covered many areas of both British and international archaeology. Societies around

bespoke geographical or historical areas tended to develop separately, such as the Palestinian Exploration Fund in 1865 or the Egypt Exploration Society in 1882.

Positioning archaeology as a science was key in this period. Development in the natural sciences continued to influence the formation of professional archaeology. Charles Darwin's evolutionary evidence in *On the Origin of the Species by means of Natural Selection* (1859) and the work of Alfred Russel Wallace stimulated a change in classification and descriptive procedures as much as the application of Darwinian ideas. Darwinian evolutionism was hugely influential when archaeology began to establish itself as a discipline in universities during the 1880s and 1890s. The advocation of progress predicated in evolutionism was bound up with ideas around the hierarchy of "races" and civilizations, with "white" European races and civilizations considered most advanced. The "mound builders" controversy in North America illustrated that these ideas were entrenched before evolutionism. A "speculative" but culturally diffusionist example of a similar belief that had serious political consequences was the "discovery" of the medieval site (eleventh to fifteenth centuries CE) in Southern Africa known as Great Zimbabwe (Robertshaw 1990). The site was "discovered" by the German explorer Karl Mauch in 1871 and his publication was followed by the surveying work of the British archaeologist J. Theodore Bent in 1891–1892. Both Mauch and Bent considered the large stone city to be too architecturally complex to be built by the African Shona people who lived in that area and claimed that it must have been built by a northern Semitic race, akin to the Phoenicians, who migrated in antiquity (Fig. 5).

This was not based on any empirical evidence. It is a sign of the increased emphasis on evidence and the professionalization of archaeology that Bent's (1892) *Ruined Cities of Mashonaland* was a popular success but criticized for "sketchy records" by scholars. Despite this the colonial impact of his archaeological theory was dramatic. Cecil Rhodes' British South Africa Company occupied the lands around the Great Zimbabwe and "the site became a symbol of the justice of European colonization, which was portrayed as the white race returning to a land that it had formerly ruled" (Kuklick 1991: 135). Although Gertrude Caton Thompson proved Bent and Mauch wrong in 1928, their views held currency amongst "white" settlers until well into the late twentieth century. Formal colonial policies and land ownership were parallel with the greater professionalization of archaeology.

International Perspectives

One of the greatest legacies of the "Speculative Phase" of archaeology though is perhaps the acquisition of antiquities for museums – an area

that would be worthy of another entry in itself. One of the pressing issues for museums today, in Europe and North America in particular, is the issue of restitution or the repatriation of antiquities from museums to source communities and nations. This is particularly pertinent to museums in Britain with regards to the British Museum. Many of the excavations carried out by explorer-archaeologists were covered by related legal agreements made within the networks of diplomatic links and "informal imperialism" that were at work during this period. Some of these agreements, such as the firman with the Ottoman Empire about the "Elgin Marbles," were made between countries or empires that no longer exist and are not recognized as legally binding by the successor modern nation state. Other collections were taken without such agreements, such as punitive expeditionary forces by the British in Ethiopia in 1867–1868, or under a system now considered defunct by the modern nation state, such as the "partage" system in Egypt.

The emphasis in debates about restitution is generally placed on anthropological items, particularly on human remains or items of religious importance, but these claims affect archaeological collections as well and not just cause célèbres such as the Rosetta Stone. The development of nationalisms and the use of heritage in defining a nation has become important in post-colonial societies and nations. Many calls for the demand of antiquities, even if not made formally, are well-known. For example, a punitive expeditionary force was sent by the British government to the Kingdom of Benin in 1897 and took intricate bronze plaques, among other items, from the city. Known as the "Benin bronzes," Nigerian officials and others have condemned their retention in various museums in Britain. There is a vast literature on this area. The point here is that the complexity of these cases requires knowledge of this "Speculative Phase" of archaeology and what impact it has on contemporary ideas about cultural knowledge and ownership.

A related area to the above is the collection, retention and display of human remains for archaeological purposes made during this phase. The overlapping of archaeology and anthropology is particularly important in this area. Skulls and other human remains were amassed for research around human development and "racial" theory in museums and related research institutions (Fabian 2010). Indigenous communities were/are particularly affected by the collection of both ancestral and recent human remains during the "Speculative Phase" and beyond. Many countries now have ethical codes around the retention and display of human remains in museums and institutions, for example the *Native American Graves Protection and Repatriation Act* (NAGPRA) in North America. In Britain the Department of Culture Media and Sport issued "Guidance for the Care of Human Remains in Museums" in 2005 which was drawn up in relation to the 2004 *Human Tissues Act* and issued on behalf of the museum sector. The *Human Tissues Act* covers material under 1000 years old but there are also growing sensibilities within the sector and amongst the public about the display of older human remains, such as mummies and bog bodies. Again this is an issue that is not simply limited to current understanding of the "Speculative Phase."

The impact of the "Speculative Phase" on forming disciplines of archaeology and classical archaeology in university museums has become of greater interest for curators trying to understand the history of their collections in order to interpret them within the history of the institution for a wider public. This can be seen in the 2011 redisplay of the Greek and Roman antiquities at the Fitzwilliam Museum, University of Cambridge, in which the collecting history and connecting disciplines of the history of art and philology are considered. The major revamp of the Ashmolean Museum at the University of Oxford, which reopened in 2009, placed the history of the collection of its objects at the center of its museum narrative, including a display on Arthur Evans in Crete that incorporated Schliemann in Mycanae and other related archaeological discoveries made before the discipline of archaeology was formed.

Another direction in Britain related to museums, both the British Museum and local museums, and local archaeological services is

the Portable Antiquities Scheme (www.finds.org.uk). The Portable Antiquities Scheme is a voluntary scheme to record archaeological objects found by members of the public in England and Wales. Finds Liasion Officers positioned at museums or archaeological services around the country actively work with metal-detector users and people within their area to record finds. This is partly due to the 1996 *Treasure Act* which means people have a legal obligation to report any finds of material over 300 years old. In some ways this heralds a return to the importance of the amateur through metal-detector users carrying out "speculative" archaeology, but combined with professional expertise and support.

Future Directions

Much of the research around the "Speculative Phase" of archaeology is relatively recent, dating to the last few decades with a surge of scholarly interest from the late 1980s. As a result there are a great many future directions for the study of this area, which are facilitated by cross-disciplinary international groups such as the History of Archaeology Research Network (HARN). Also, as "International Perspectives" records, there are many contentious areas that attract wider public attention needing careful examination and reflection. The future directions highlighted here are just a few of many possible areas.

A current and future direction of work is on the influence of "showman archaeology" from the "Speculative Phase" to the present. The idea of "showman archaeology" (and the male gendering is a feature of interest in itself) has never really disappeared even after the professionalization of archaeology and the formation of different disciplinary areas. Explorer-archaeologists cultivated a public persona to generate more publicity to get recognition for their excavations, objects and themselves. They needed to do this before there was formal government and institutional funding. Arguably "showman archaeology" became even more important in the film and television age as it gives a personal focus and narrative to the distant past. Mortimer Wheeler was one of the first to use film reel to raise awareness of excavations in Britain in the 1920s and 1930s, and then enhanced his celebrity by appearing on radio and TV quiz shows in the 1950s and 1960s. Wheeler himself stated that he did this to gather funding and public interest. With the *Indiana Jones* film franchise and other "archaeological" films and games such as *Lara Croft: Tomb Raider* and *National Treasure*, archaeology and adventure are molded together in public consciousness. Zahi Hawass, the former Minister of State for Antiquities in Egypt, presented himself as an "explorer-archaeologist" on television and to the public, even merchandising related clothes. Arguably by doing this he attracted more funding and tourists to Egypt, but along the way also generated fierce criticism.

An important future direction is consideration of the role of the workforce in the archaeological excavations carried out during the "Speculative Phase," both the people recruited from the local area around the excavation site and those drafted in by the leading archaeologist to take part, such as members of the armed forces. The continued focus on the explorer-archaeologist neglects the importance of these other people that were directed on excavations, particularly those in colonial or "informal" colonial conditions, and their role in both finding and interpreting material (Quirke 2010). Researching this information is hard, particularly for the "Speculative Phase" in which formal lists of workforces are not frequently retained in archives. However, archaeological reports and journals as well as other media from the period can often give information about the workforce. This information would add to greater understanding about the workforce's role in the "Speculative Phase" of archaeology and give a more nuanced account of the role of European and American explorer-archaeologists and the institutions that supported them (Fig. 6).

Research should be continually interrogating how many of the assumptions made during the "Speculative Phase" are still with us, implicitly or explicitly, particularly those based on out-moded

"Speculative Phase" of Archaeology, Fig. 6 Hussein Osman excavating at Abydos, 1899–1900 (On a Flinders Petrie excavation). Photograph Album belonging to Margaret Murray. Petrie Museum of Egyptian Archaeology Archives

classification systems and ideas of "racial" hierarchies. It is important to point out that the contemporary illicit trade in antiquities, for example, continues to be reliant on speculation in every respect.

Squash: Origins and Development

Tim Denham
Archaeological Science Programs, School of Archaeology and Anthropology, ANU College of Arts and Social Sciences, The Australian National University, Canberra, ACT, Australia

Basic Species Information

Multiple species of *Cucurbita* underwent domestication in the Americas (e.g., Sanjur et al. 2002). The most significant group of crop plants is descended from *Cucurbita pepo*, including pumpkins, acorn–summer squashes, marrow, and zucchini. Today, these vegetables have multilayered cultural associations and significance in the regions around the world in which they are grown.

The reconstruction of the processes involved in the early stages of domestication of *Cucurbita pepo* is complex. However, several key stages of early domestication in the Americas have been documented archaeobotanically and, together with genetic data (e.g., Decker-Walters et al. 1993; Sanjur et al. 2002), suggest multiple "independent" domestication events.

Major Domestication Traits

The archaeobotany of squash domestication has been based on macrobotanical remains of rind fragments, fruit stems or peduncles, and seeds (Smith 2006). Wild and cultivated forms of *Cucurbita pepo* are differentiated in archaeobotanical assemblages based upon seed size and the size and morphology of peduncles. Individual specimens are then directly radiocarbon dated (AMS) to provide a robust chronology, thereby avoiding taphonomic problems arising through the dating of archaeobotanical finds by association (Smith 1997; also see Dillehay et al. 2007). Using this method, two independent domestications of squash have been inferred: "the pumpkin lineage (*Cucurbita pepo* ssp. *pepo*) in Mexico by 10,000 years ago, and the acorn–summer squash lineage (*Cucurbita pepo* ssp. *ovifera*) in the eastern United States by 5,000 years ago" (Smith 2006: 29).

Timing and Tracking Domestication

A large-seeded form of *Cucurbita pepo* was cultivated in the vicinity of Guilà Naquitz Cave in the Oaxaca Valley of Mexico around 10,000 cal BP (Smith 1997, 1998, 2006). At this time, people also harvested wild *Cucurbita* gourds. The increase in seed size is characteristic of domesticated *Cucurbita pepo* ssp. *pepo* and is considered "good evidence for the adaptive syndrome of domestication—an automatic adaptive response by squash plants to new seed bed selective pressures associated with deliberate and sustained planting" (Smith 2006: 28). By 8,400 cal BP, over 1,000 years after initial cultivation, the increased size of fruit peduncles suggests selection for larger fruits, with a steady rise in fruit size continuing thereafter (Smith 2006).

Another large-seeded form of *Cucurbita pepo* has been identified and inferred to have been cultivated in the vicinity of Phillips Spring, Missouri, United States of America, around 5,000 cal BP (Smith 2000, 2006). The archaeobotanical assemblage indicated exploitation of wild *Cucurbita* gourds and domestication of *Cucurbita pepo* ssp. *ovifera*. Variations in fruit morphology, fruit size, and rind thickness suggest sustained human selection for c. 2,000 years after initial domestication of *Cucurbita pepo* ssp. *ovifera* (Smith 2006: 29). Fritz (2007) and others have postulated that acorn–summer squash was dispersed and planted in North America before 5,000 cal BP.

Microfossil techniques, principally phytolith analysis, have also proven useful to document the exploitation and dispersal of squash in the Americas (e.g., Piperno et al. 2009). Many species of *Cucurbita* were widely exploited by foragers and farmers in the Americas (Piperno and Pearsall 1998), making the differentiation of species and domestication status important aspects of phytolith research (e.g., Piperno and Stothert 2003). Additionally, gourd and squash artifacts have

themselves provided evidence, in the form of starch residues, for other plants consumed during Preceramic times in the Americas (Duncan et al. 2009).

By the time of European conquest and colonization, squash was part of the maize–bean–squash diet that sustained communities across the Americas. Bruce Smith (1998: 147) has stated that this domesticate triad was cultivated from "Argentina to Ecuador, up through Central America and Mexico, and as far north as southern Ontario" (Smith 1998: 147). Not only were these crops nutritionally balanced, but they also complemented one another agronomically and were beneficially planted together in mixed plots.

Stahl, Peter W.

Deborah M. Pearsall
Department of Anthropology, University of Missouri, Columbia, MO, USA

Basic Biographical Information

Peter William Stahl is an archaeologist and zooarchaeologist with primary interests in New World archaeology and ethnography and a

geographical emphasis in the Northern Andes and tropical lowlands of South America. Stahl was born December 10, 1953, in Val-D'Or, Quebec, Canada. He is married to Ann B. Stahl, an anthropological archaeologist with research interests in Africa. They have two children.

Peter Stahl received his B.A. in 1975 from the University of Toronto (Victoria College) and M.A. in Archaeology in 1978 from the University of Calgary, where he worked with J. H. Kelley. He attended the University of Illinois, Urbana-Champaign, for the Ph.D., working with D. W. Lathrap. Stahl's dissertation, *Tropical Forest Cosmology: The Cultural Context of the Early Valdivia Occupations at Loma Alta*, was completed in 1984. After positions as a Research Fellow at the University of California, Berkeley (1984–1985), and University College, London (1985–1988), Stahl began a long association with the Department of Anthropology at Binghamton University (SUNY), Binghamton, New York, from which he retired in 2011 as Director of the Archaeological Analytical Research Facility and Professor of Anthropology. He is currently with the Department of Anthropology at the University of Victoria.

Major Accomplishments

Peter Stahl has practiced zooarchaeology – the identification and interpretation of preserved bone assemblages from archaeological sites – for some 35 years. Zooarchaeology assumed a prominent role in archaeology during the final quarter of the twentieth century with the emergence of cultural ecology and ecological anthropology (Reitz and Wing 2008: 11–30). Stahl has participated in significant developments in each of the facets of modern zooarchaeological research, methodology, anthropological research, and biological research.

As faunal data have become increasingly important in archaeological research, understanding the processes of accumulation and deposition of faunal remains, or taphonomy, became a central methodological issue in the interpretation of archaeological faunal assemblages. Stahl has contributed to this line of research. For example, he studied the structural density of camelid skeletal elements to explore the archaeological correlates for *ch'arki* (dried meat) production in the prehistoric Andes, concluding that faunal data from the Chavin site, Peru, did not support the consumption of imported *ch'arki* (Stahl 1999). His study of faunal materials from a large bell-shaped pit at the Pechichal site, Ecuador, is a textbook illustration of how understanding assemblage accumulation and deposition allows inference of both hunting practices and ecology, the latter inferred from the natural histories of naturally entrapped fauna (Stahl 2000).

Investigating relationships between human populations and animals contributes to anthropological research in diverse and significant ways. Peter Stahl's contributions in this area are many. He has most recently investigated the association between humans and native foxes in early Holocene South America, arguing that humans had an intimate relationship with foxes that predated the introduction of domesticated dogs and which represented an early example of an indigenous cosmology that considers selected animals as social beings (Stahl 2012). Native South American domesticated camelids and *cuy* (guinea pig) appear in Andean Ecuador well before the area was occupied by the Inca Empire, but were not domesticated there (Stahl 2003). Stahl argues from the rarity and the elite context of these finds in Ecuador that animal domesticates were part of ancient terrestrial and later maritime trade linking Ecuador and the Central Andes of Peru, trade controlled by, and benefiting, elites.

Stahl is an articulate advocate for revising standard Amazonian archaeology. In his 2002 invited article in *The Review of Archaeology*, he argues cogently for a perspective on Amazonian prehistory that recognizes the importance of historical circumstance in shaping prehistoric and contemporary cultures and that emphasizes the environmental, cultural, and agricultural heterogeneity of the lowland tropics. He advocates research using complementary sources and methodologies, which "...demonstrate the potential of an integrated anthropological research paradigm for producing nuanced and sophisticated interpretations of a least-known continent and people" (Stahl 2010: 218).

Peter Stahl was an early voice for the contributions of archaeology (1996) and zooarchaeology (2008) for exploring issues related to Holocene biodiversity in the Americas. The archaeological record of environmental transformations during the 10,000 years of the Holocene, while far from perfect, illustrates the dynamism of prehistoric biodiversity and the interplay of environmental events and anthropogenic effects. Zooarchaeologists can contribute greatly to understanding biodiversity through the study of past human landscapes; this is the perspective of historical ecology:

> When we consider humans as conservationists and resource managers or epiphenomenal optimal foragers, we avoid the real position that indigenous populations created the very ecosystems that we wish to conserve. . .. Archaeologists, by definition, excavate and explore anthropogenic landscapes through time and space; therefore we are historical ecologists. (Stahl 2008: 12, 13).

Stakeholders and Community Participation

Paul A. Shackel
Department of Anthropology, University of Maryland, College Park, MD, USA

Introduction

From the 1970s, there has been growing momentum in the discipline of archaeology to share significant discoveries with the public. The types of public archaeology programs have changed since this time, from public tours, to public participation at archaeology sites, to stakeholders playing a role in the development of research programs in their communities. Barbara Little's (2002) edited volume on the *Public Benefits of Archaeology* shows how archaeology is becoming much more broadly perceived by the public and practitioners. She writes that archaeologists are increasingly using the discipline for "purposes of education, community cohesion, entertainment, and economic development" (Little 2002: 1). Following is a brief overview of the development of community archaeology programs and the archaeologists' changing role with stakeholder. With several international examples, this overview provides a conceptual framework for why it is important to work with stakeholders and the benefits to the discipline and community. It does not provide a complete overview of the literature. An interactive wiki on community archaeology – http://en.

wikipedia.org/wiki/Public_archaeology – furnishes an overview of the growing literature on this topic.

Definition

Community archaeology involves communities in the planning and the implementation of the project. The goal of community archaeology is to make a difference and/or a contribution to the community. Noel Chrisman (2006: 168) provides seven broad principles for scholars collaborating with communities. They are valuable for helping to develop bonds with communities and descendant groups. To summarize, these principles state:

1. Proposals and procedures must be consistent with community's culture, values, and beliefs.
2. Collaboration with the community is necessary in identifying its wants and needs.
3. The participation of community members is integral to realistic planning, delivery, and evaluation of a project.
4. Collaboration with existing organizations and their leaders is a must.
5. The design and implementation of projects must make sense to the community.
6. Anthropologists must respect the people with whom they work.
7. Anthropologists must be agents for change by working with people, not on them.

Key Issues/Current Debates/Future Directions/Examples

The discipline's growing ethical accountability encourages us to include stakeholders in the decision-making process of the research design, fieldwork, and, at times, the interpretation of the archaeological findings, thereby empowering communities to identify and connect to their past. The basis for a well-run community archaeology program is sharing the decision-making processes between the archaeologist and the stakeholder. The archaeology program at Ozette, a late prehistoric/historic whaling village in northwestern Washington State, is one of the earliest internationally known community archaeology programs. The Makah Tribal Council invited archaeologists to examine archaeological features uncovered by a mud slide. The project ran from 1970 to 1981 with the Makah Tribe playing a major role in the decision-making process along with the archaeologists throughout the project (Kirk and Daugherty 1974). At about the same time, Australian archaeologists were developing a dialogue with indigenous communities. These communications developed as the government recognized that indigenous people had the right to control their cultural resources through the "land rights" movement. This form of inclusion was more about obtaining consent for research rather than developing broader dialogue, greater community participation, and sharing in the decision-making process (Greer et al. 2002: 266).

The sharing of the decision-making process and the building of social capital between different communities and between community and professional is an important matter for archaeologists to consider when working with communities. There are, however, different views about what social capital is and how it can be used. For instance, sociologist Pierre Bourdieu (1977) explains that social capital can be used to produce or reproduce inequality. Bourdieu demonstrates how individuals can gain power through social connections. Robert Putnam (2000) uses the concept in a different way. He shows how social capital produces civic engagement, which can lead to a broad societal measure of communal health. Social capital develops in collectives and it is important for building and maintaining democracy. Putnam believes that social capital can be measured by the amount of trust and reciprocity exists in a community or between individuals.

Putnam also writes about bonding and bridging social capital. Bonding social capital is exclusive and homogenizing and is often exclusionary. Bridging social capital refers to the networking between socially heterogeneous groups. It can help create many benefits for societies, governments, individuals, and communities. The relationships and networks that bring people and

communities together are essential for a healthy self and a vital community (Hirzy 2002: 14). Connectedness through social networking is essential for the social, physical, and economic endurance of a community, and a sense of heritage can develop with consensus building between the different stakeholders.

In many ways, Bourdieu and Putnum's divergent views of social capital can help describe many public archaeology programs and how archaeologists view community participation in them. If a community archaeology program is developed from the outside, or the top down, it stands the chance of alienating people by not recognizing the inequalities that exist in the contemporary community. For instance, when a corporation or a university comes into an unfamiliar place, creates a research design for excavations, and develops a public archaeology program without input from the local population, they are creating a strategy that can alienate a community and separate them from their past. Democracy is not in play, and bridging between communities is not effective. When outsiders control the meaning of a community's past and only emphasize the exotic, or reinforce the consensus history, the public interpretation of an archaeology site stands a greater chance of alienating and disenfranchising the local community.

In 1997, Karolyn Smardz (1997: 103) wrote that archaeology should "stop taking archaeology to the public for archaeology's sake and start doing it to meet the general public's educational, social, and cultural needs." Civic engagement can be one way to address this imbalance. The civic engagement movement in archaeology is about the creation of a shared past. It is a growing trend in many professions, and its implications run much deeper than traditional public outreach programs. Civic engagement can take many forms and designs, but in all cases, it is a collaborative effort that does not presume what the community needs. Therefore, there is a deliberate shifting from the practice of *outreach* to the practice of *inreach*. *Inreach* is the practice of working with communities on research projects and reinforcing the ideals of collaboration. It is a way of making the discipline relevant to a broader audience. *Inreach* also becomes important when we challenge the consensus views of the past. For instance, archaeologists working with the Northern Cheyenne developed an important collaborative project that challenged the consensus history of a significant event related to their tribal history. Working with the tribe, archaeologists set out to find the escape route and eventual slaughter of many Northern Cheyenne. History relates that they escaped their imprisonment at Fort Robinson and were pursued by the US Calvary. Commonly held accounts, supplied by the military, differed significantly from Northern Cheyenne oral history regarding routes taken. Through this collaborative work, archaeological findings confirmed the correctness of oral history accounts related to the Outbreak of 1879, which differed from the military account. This work allowed for the commemoration of this trail and massacre (McDonald et al. 1991).

Community archaeology programs that develop on a grassroot level can help foster a form of democracy building by creating connections between different groups to present a common past. Carol McDavid (2004: 164–165) proposes that archaeologists should use available media, like the internet, to hold conversations between archaeologists and the public rather than developing presentations for the public. Community participation can become part of a democratizing process whereby the control over the interpretation of the past is decentralized and made more egalitarian. Pearson and Ramilisonina (2004: 236–237) use case studies from the Outer Hebrides and southern Madagascar to propose that archaeologists can work hand-in-hand with indigenous groups, breaking down the cultural and political barriers and work with a common interest in the study of the past.

There are many examples of archaeologists working with American Indian communities, and recently there has been a profusion of historical archaeologists engaged in local communities and making a difference, some addressing questions related to social justice (Swidler et al. 1997; Dongoske et al. 2000; Watkins 2001; Little 2002; Derry and Malloy 2003; Shackel and Chambers 2004; Colwell-Chanthaphonh and Ferguson

2007; Little and Shackel 2007). These works include many of the principles noted by Chrisman.

Moser et al. (2002: 229), working in the ancient Port of Quseir, Egypt, detail a unique community project. Traditionally, outsiders have come into Egypt to perform archaeology and the local communities have been excluded from the discovery process. They have also been omitted from developing their own local heritage. The project at the Port of Quseir provides another set of guidelines for the development of a community archaeology program. They include:

1. Communication and collaboration
2. Employment and training
3. Public presentation
4. Interviews and oral history
5. Educational resources
6. Photographic and video archives
7. Community-controlled merchandising

Much like other community archaeology programs being developed around the world, this archaeology project has developed whereby the local community can benefit from the research by participating in the development of their local heritage and also receiving financial gains (Marshall 2002).

Community groups and organizations have significant assets that can lend to the success of any archaeology program. Communities have "a deep knowledge of their communities and constituencies, the capacity to seek nontraditional outcomes, and experience with community building. We have to resist the impulse to dictate the agenda, and ensure that all questions relating to attitude, approach, ownership, access, and trust are resolved to everyone's satisfaction" (Kertzner 2002: 41; also see Archibald 2002: 3). While some archaeologists are increasingly taking into consideration the needs and desires of the communities, the goal of inclusiveness and developing bridging social capital can be a complex matter, especially when research strategies and interpretations are negotiated with the various stakeholders. Choices are made about research goals, issues of significance, and what issues, interpretations, and conclusions are worth sharing with the larger audience. In every project, archaeologists make decisions about the politics of their research agenda. They are faced with questions of either supporting the consensus history or changing the status quo.

Lisa Breglia (2007: 98), working with communities in the Yucatan, cautions us to recognize that "1) archaeology does not always represent what the local people understand as their heritage; and, what's more 2) public or community outreach, though it may be practiced with the best of intentions always carries the potential danger of ethnocentrism." A case study of a collaborative project whereby the archaeologists were in danger of not understanding the local heritage is situated in Saskatchewan, Canada. There, thousands of Doukhobors fled Tsarist persecution in Russia in 1899. One sect of Doukhobors practices communalism, pacifism, vegetarianism, and the avoidance of alcohol and tobacco. Archaeologists found alcohol bottles and butchered bones in the archaeological assemblage. The descendants were upset with the findings because they were proud of their ancestor's convictions. One descendant told the story that her grandparents had to feed the non-Doukhobor farm workers meat, or they would leave the farms. Therefore, the descendant proposed that the evidence of meat was a product of her grandparents serving farm hands, rather than her grandparents breaking religious prohibitions (Brooks 2007).

Archaeologists can take a role in either a participatory or a collaborative approach. The former develops from the outside, when the latter is part of a shared activity. An increasing number of archaeologists are committed to the idea that communities have a sense of their own past and they want to be part of decision-making process regarding their own heritage development. This changing perspective in the discipline is paralleled by changes in anthropology as a whole, and while the discipline has changed significantly, archaeologists are only beginning to realize the importance of community involvement. Community participation means that scientists are no longer the cultural brokers. Practitioners are beginning to recognize that many histories can exist in any

one place, and these stories of the past are continually being shaped and reconstructed. Archaeologists are in a good place to address these changing perspectives and they need to respond effectively to these challenges and opportunities. As practicing archaeologists, our charge can be to help change society for the better.

Standardization, Storage, and Dissemination of Environmental Archaeological Data

Sarah Whitcher Kansa and Eric C. Kansa
Open Context, The Alexandria Archive Institute, San Francisco, CA, USA

Introduction

Archaeological researchers rely on computers for many data collection, analysis, presentation, and scholarly communication needs. Through the Web, researchers can now disseminate all the information they collect in excavations and analyses, not just the resulting synthetic reports. However, while technologies can store and transmit these data, approaches to data documentation, quality improvement, semantic description, and data preservation see active research and development.

Definition

Most datasets are now "born-digital," giving the researcher community new opportunities for sharing them via the Web. Despite hesitation and incentive concerns (see Harley et al. 2010), there is a growing expectation for access to primary datasets so that other scholars can reanalyze them with new questions and perspectives (Kansa and Kansa 2011). However, as data sharing assumes greater primacy in professional communications, researchers need supporting services to adequately describe and document, preserve, disseminate, and understand and reuse digital data.

Documentation, use of appropriate standards, storage, and dissemination are all aspects of "data stewardship." These help ensure that data are sufficiently described and preserved in a way that allows for well-informed future use. To guide researchers in data stewardship, the Archaeology Data Service (http://archaeologydataservice.ac.uk/) and Digital Antiquity (http://www.digitalantiquity.org/) have authored invaluable guides to good practice (http://guides.archaeologydataservice.ac.uk/). These guides introduce metadata ("information about information") requirements, recommended practices for data formats (especially recommendations for use of open and nonproprietary file formats), and archival practices.

Key Issues/Current Debates/Future Directions/Examples

Standards

The term "environmental archaeological data" encompasses a wide range of data pertaining to the study of past human interactions with the environment. These data come from highly multidisciplinary investigations and analyses, including (but not limited to) paleobotany, zooarchaeology, soil chemistry, micromorphology, archaeomalacology, geomorphology, and isotopic analyses. Datasets vary widely in terms of size and character. Some data result directly from the output of instrumentation, and others are created by individual researchers and may include both quantitative and qualitative data.

In order to facilitate informed reuse and preservation, all of these data need alignment to certain standards. However, there are many kinds of "standards." Some standards refer to technical specifics of data formats, instrumentation settings, and the like. Metadata description and documentation represents another type of standard. Finally, some types of standards reflect concerns over the appropriateness of data collection methods and data quality. In all cases, conforming to

community expectations regarding standards facilitates data reuse.

As is the case with most archaeological data, metadata about context, broadly defined, is required to make use of paleoenvironmental datasets. Given that resources and human effort are scarce, certain forms of documentation should be prioritized. For example, published data should include some fundamentals, including discussion of methods, research aims, and data collection practices. Baseline contextual information (geographic, stratigraphic, and chronological) also needs to be provided. Shared data need to be decoded (or coding systems need detailed documentation) to facilitate informed reuse and comparison with other datasets. In many cases, it will be important to provide key technical metadata documenting the specifics of instruments used, geographic coordinate systems, other aspects of data collection methods, and information about postprocessing software and algorithms. In addition, the "scholarly" provenance and context is also critical. Who collected the data and under what sponsorship and institutional setting? What are the licensing conditions on sharing and using a dataset? Many of these attributes are recorded using the Dublin Core metadata standard.

Different repositories may have different specific technical requirements for expressing these metadata. Variability in data documentation results from different institutional settings in research as well as different research needs and traditions. Also, data documentation and metadata needs will not likely stay fixed. Researcher needs and expectations change, and this will drive changes in how data need to be documented. Thus, while standards can be very useful in helping others understand and reuse data (Atici et al. 2012; Kansa et al. 2014), data repositories and dissemination services need to accommodate diverse and changing needs and expectations in different disciplinary communities. Thus, standards and research designs will coevolve, particularly once data dissemination and reuse becomes a more commonplace practice.

Standards can be extremely useful for meta-analyses and collaborative research (see, for example, Arbuckle et al. 2014). While many researchers recognize the value of shared standards, data are often very heterogeneously developed and described, as noted above. In many areas of environmental archaeology, there are only a few instances where researchers adhere to common data collection standards and protocols. For instance, the suite of measurements proposed by Angela von den Driesch in her 1976 *A Guide to the Measurement of Animal Bones from Archaeological Sites* is widely used by zooarchaeologists. However, though many researchers may use this protocol; they may express and encode these measurements in very different ways.

Because it is unlikely (and even ill-advised) for researchers to use only one data collection protocol and database structure, other methods need to be developed to relate researcher datasets together. Most commonly, researchers use ontologies to relate different datasets together. Ontologies are formally described conceptual systems, usually expressed in such standards such as RDF/OWL or RDF/SKOS. Ontologies define different concepts and various logical relationships between concepts. Different datasets can be related to a common ontology so that these data can be compared, even though these datasets individually may have idiosyncratic terminologies and organizations. It is often a goal to use the logical rules and relations expressed in an ontology to make inferences on datasets related to the ontology. Digital Antiquity, with the tDAR system (http://www.tdar.org/), is doing pioneering research in relating datasets together using different ontologies. Their initial experiments have focused on zooarchaeology. This approach toward data integration is more feasible in this subdiscipline because of the widespread use of common data documentation conventions.

The use of ontologies in archaeology varies widely. Open Context (http://opencontext.org) uses a highly generalized ontology to model and index all data it publishes. In addition, Open Context also uses more specific ontologies and controlled vocabularies to relate different datasets published by Open Context with data curated across the Web. On the other hand, tDAR

facilitates use of ontologies for users to integrate data within tDAR. But tDAR does not relate all data it archives to a common ontology, which means search and indexing services emphasize metadata, and less the content of tDAR archived data. Different ontology strategies have different costs and benefits. Generalized ontologies lack the specificity needed for many research applications, while specific ontologies can often be very complicated, difficult, and costly to apply. Research applications will probably help identify the "right" mix between generalized and specific ontological models. In the case of zooarchaeology, some aspects of recording probably can and should see more specific modeling (such as taxonomic identification, bone element identification, and fusion data), while other aspects of zooarchaeological data may see less need to for such specific modeling.

In addition to ontologies, the architecture of data repositories in environmental archaeology plays a role in data interoperability and reuse. tDAR offers powerful features to give researchers options to use multiple ontologies to relate different datasets found within the tDAR repository. Open Context takes a different approach by exposing data on the Web to make it easier to use with Linked Open Data (LOD) methods. With LOD, Open Context data can be referenced to common vocabularies and ontologies via Web URIs (stable Web addresses that serve as identifiers) and related to other data sources published to the Web. For example, Open Context uses LOD methods to identify biological taxa according to Web identifiers published by the Encyclopedia of Life (http://eol.org), a major database of biological taxa. Again, the different approaches taken by tDAR and Open Context involve different sets of tradeoffs (see also Sheehan 2015). Open Context's use of EOL identifiers helps relate data across the open Web, enabling researchers to reference and use data curated by large, global, and interdisciplinary communities. On the other hand, tDAR's ontology tools make it more convenient for users to experiment with different ontologies but only datasets found within tDAR. While different, these approaches are not mutually exclusive and can be complementary. These differences highlight how the semantic interoperability of environmental archaeological data remains an active area of research.

Explicitly-recorded data documentation and formal ontologies are important and often critical needs. However, they are not the only issues involved in data preservation, reuse, and interoperability. Human factors are also critical needs. The background and tacit knowledge of experienced specialists can be invaluable to understanding an old dataset, even without detailed documentation (see Atici et al. 2012; Faniel and Yakel 2017). In addition to understanding domain-specific problems in data collection practices and research methods, the research community also needs to develop informatics skills and expertise, so that they can better understand the use and limitations of different approaches to semantics and data integration. For example, the importance of reproducible research, or sharing both data and the analytical steps used to process the data, has become a concern in light of increasing interest in data sharing in the archaeological community. Python "data science" code libraries and R language offer two examples of open source statistical analysis and visualization software that are popular among the growing number of researchers engaged in reproducible research (Marwick 2016).

Preservation and Dissemination

Researchers tend to have poor data curation practices. Most individuals keep data on personal hard drives, perhaps backing them up intermittently on some form of external digital media. Such devices are prone to failure and obsolescence in very short time horizons. Not only do digital media degrade quickly, but file formats and supporting software also rapidly change. For digital data to be usable for the long term, they need continual and active curation by dedicated professionals.

Formal digital repositories have developed specifically for archaeology, including the Archaeology Data Service in the UK and Digital

Antiquity in the USA. Both of these organizations actively curate data, migrate files to new formats as required, and perform other vital repository functions. A somewhat different approach is taken by Open Context, where it does not act as a digital repository itself, but rather archives data with the digital repository maintained by the University of California, through the California Digital Library (http://www.cdlib.org/). Digital repositories, whether discipline-based or based in a "memory institution" like a library, play an essential role in the long-term secure storage of environmental archaeological data. At the same time, data preservation is complemented by data reuse. Data that sees active use will likely see more investment in preservation.

With regard to data dissemination and reuse, professional expectations are rapidly evolving. Though archaeologists routinely manage complex and highly structured digital data, dissemination and communication objectives traditionally remained decidedly oriented toward print or digital analogs of printed documents (such as PDFs). The prevailing norms and expectations for print publication mean that researchers tend not to share the primary data they collect, thus precluding reuse and reexamination of these data. Though data sharing is still rare, it is gaining traction as a key issue in scientific communications (Costello 2009; Nature Editors 2009) and an increasing number of publishers request supporting data to be shared with conventional publications. Scholars have discussed a multitude of semantic (Kintigh 2006), technological (Snow et al. 2006), data preservation and longevity (Richards 2004; Carraway 2011), intellectual property (Kansa et al. 2005), and professional incentive concerns (Costello 2009; Kansa 2010) regarding data sharing. Increasingly, funders of research expect greater data professionalism, archiving, and transparency. For archaeology in the US, the National Science Foundation set early expectations in 2010 by requiring a "data management plan" from grant-seekers (see NSF press release on May 10, 2010: https://www.nsf.gov/news/news_summ.jsp?cntn_id=116928).

Since use can promote data preservation, the research community also needs innovative approaches in scholarly communication that promote data dissemination and reuse. Many of the data preservation repositories discussed above also emphasize services for data dissemination and reuse. Different dissemination services require different levels of investment in data documentation and data quality verification and improvement. As discussed above, common data and semantic standards can help make data dissemination and reuse much more efficient. However, semantic standards can be complex and time-consuming to apply, and overly rigid or misapplied standards can also constrain interpretive choices and inhibit methodological innovation. Therefore, the application of different metadata and semantic standards is not necessarily straightforward, and data dissemination services will vary in their expectations.

Besides standards alignment, data dissemination may also involve some degree of editorial review and quality improvement. In some environmental science disciplines, journals require authors to deposit the data related to their articles in Dryad (http://datadryad.org), a disciplinary data repository. While journal editors and reviewers may or may not review the actual datasets deposited in Dryad, policies requiring the dissemination of datasets aim to improve the scientific reproducibility of the analyses and interpretations presented in journal articles. So far, no archaeological journals require dataset dissemination, but the Digital Antiquity and Open Context teams are in active discussions with various archaeological publication venues to encourage such dissemination.

In the case of Dryad, most datasets entering this repository supplement the content of a journal article. This approach helps align researcher incentives, which reward journal publications, with community interest in data dissemination and preservation. However, this approach may have a disadvantage in that datasets are of secondary importance and are shared mainly to comply with policy requirements. These data may not be

reviewed or subjected to editorial scrutiny, and they may not see much effort in data cleanup or documentation beyond the minimal requirements of the repository.

Another approach to data dissemination is to make data publication a primary goal of scholarly communication in itself. If data dissemination provided some of the same professional rewards and recognition as conventional journal and book publication, then researchers may invest more effort in improving data quality and aligning data to appropriate standards. Editorially supervised "data publishing" models can make data dissemination reach the levels of quality needed to enable confidence in reuse (see Costello 2009). Editorial review processes may help researchers improve data integrity and intelligibility, promoting greater data quality and facilitating informed reuse. The Journal of Open Archaeology Data (http://openarchaeologydata.metajnl.com/), Internet Archaeology, and Open Context are currently developing data publishing services where datasets see editorial and peer review prior to dissemination.

It is likely that multiple models for data dissemination will be needed to serve the needs of environmental archaeology. In some cases, data repositories will take data directly from researchers, and in other cases data dissemination may follow more elaborate editorial review and quality improvement processes. Appropriate dissemination choices will vary depending on the nature of the data. There may be less need for editorial review for data automatically generated by instrumentation, whereas editorial processes may be more appropriate for data manually created by researchers.

However, in all cases, the goal of data sharing and archiving is to facilitate reuse, possibly including integration of data from multiple sources. In order to facilitate data reuse, the research community needs to pay particular attention to the legal and licensing requirements of data reuse and interoperability. Copyright and other intellectual property restrictions may greatly complicate, if not altogether prohibit, many uses of data expected by the scientific community. To encourage reuse, datasets need to be released either to the public domain, or under very liberal and open licensing conditions. For instance, Digital Antiquity and Open Context both require deposit of data under the Creative Commons Attribution license (https://creativecommons.org/licenses/by/4.0/), which freely permits reuse provided attribution is provided to the data creators. Dryad mandates even greater openness, requiring dedication of datasets to the public domain using Creative Commons' CC0 "no rights reserved" framework (https://creativecommons.org/share-your-work/public-domain/cc0). Use of Creative Commons licenses is especially encouraged because these widely used standard licenses facilitate legal interoperability of data. In addition, Creative Commons licenses are also represented as standard metadata, facilitating the discovery and explicit identification of legally interoperable content.

Stanish, Charles

María Cecilia Lozada
Department of Anthropology, The University of Chicago, Chicago, IL, USA

Basic Biographical Information

Charles Stanish was born in Pittsburg, Pennsylvania, in 1956. His interest in past societies developed as a high school student when he was introduced to Ancient Rome and Greece. This initial passion continued to his college years at Pennsylvania State University where he was introduced to ancient civilizations in Mexico and Central America by William T. Sanders, one of the leading Mesoamericanist of his time. Continuing his graduate education at the University of Chicago, Stanish studied under Don Rice, initially focusing his research on Maya sites in Guatemala. Due to political instability in Central America at the time, Stanish was invited in 1982 by Andean archaeologist Michael E. Moseley to work in the South Central Andes. In Peru, he worked on political economies of Andean societies, and this research served as the basis for his dissertation and postgraduate studies.

Completing his PhD in 1985, Stanish taught at the University of Illinois of Chicago. He joined

the Field Museum in Chicago in 1998 and served as chair of the Department of Anthropology 1994–1998. In 1998, Stanish moved to UCLA where he became the director of the Cotsen Institute of Archaeology at UCLA (2001–2016), and where he has mentored multiple students both at the undergraduate and graduate levels. Stanish was elected as a fellow of the American Academy of Sciences in 2006 and a member of the National Academy of Sciences in 2010 in recognition of his unique contributions to anthropology. He is currently the editor in chief of *Ñawpa Pacha*: Journal of Andean Archaeology and member of the editorial board of the Chilean journal *Estudios Atacameños.*

Major Accomplishments

Stanish emerged as a dominant figure in Andean archaeology in the latter years of his graduate career. The extended version of his dissertation was published under the title of *Ancient Andean Political Economy* (1992), and the book represents one of the first attempts to evaluate systematically John Murra's ethnohistorical model of "ecological complementarity" in the Andes from an archaeological perspective. In this book, Stanish examines the rationale of Murra's paradigm in multiple, distinct contexts, and in the process creating a much needed theoretical framework that critically examine indigenous economic systems in a global context. Based on the excavation of 17 pre-Hispanic sites in the Otora branch of the Moquegua drainage and comparison with data published from the Titicaca Basin, Stanish documents economic complementarity between highland and lowland societies as was originally proposed by Murra. In addition, he acknowledges a competing model of resource exchange between coastal communities based on craft specialization advocated by the Peruvian scholar María Rostworswski. In this context, he discusses the evolution of such systems within various sociopolitical contexts at least a hundred years before they were historically documented. While conducting his field research, Stanish warned against the unwarranted use of mortuary contexts, which represented highly ritualized behavior, to address questions regarding other spheres of ancient behavior, such as political economy. In his view, the methodological inclusion of household archaeology was imperative as it represented a fundamental unit of analysis that, unlike the funerary data, provided direct evidence of past economic activities.

Following his interest in the reconstruction of past economic models, Stanish initiated a multifaceted research program in the Lake Titicaca Basin. For about two decades, he systematically surveyed and excavated pre-Hispanic sites to study the origins and evolution of complex societies through 3000 years. In his seminal book *Ancient Titicaca: The Evolution of Complex Society in Southern Peru and Northern Bolivia* (2003) he integrates a variety of geological, ethnohistorical, linguistic, and archaeological sources to reconstruct the rich prehistory of the Titicaca Basin from 2000 BCE until the arrival of the Spaniards in the sixteenth century. The most significant result of this effort is, perhaps, the detailed interpretation of the local economies and political systems that lead to the emergence of the Tiwanaku polity. Unlike previous Tiwanaku studies, Stanish's rigorous diachronic studies suggested that multiple factors led to the development of the Tiwanaku polity in 400 CE, including competition for economic resources, political power, and ideological dominance among rival political entities throughout the basin. His theoretical framework and robust archaeological data became a model for comparative studies in other sociopolitical settings both within and outside the Andes. Beginning in 2011, Stanish shifted his regional research focus to the coastal valley of Chincha, where he continues to ask challenging questions and apply innovative multidisciplinary techniques in the field. Along with a team of collaborators and students, he is currently evaluating the emergence of early complex societies in coastal settings in an effort to evaluate the convergence or divergence of factors that lead to the development of the state in the Andes.

Apart from the impact of his research on understanding complex societies in the Andes, Stanish has had an equally important impact on issues

relevant to the archaeological community at large. In 2009, Stanish described how the emergence of eBay reduced the market for looted archaeological materials by supporting local artisans who produce faithful reproductions of antiquities which are sold for less, and are accessible to a wider international audience. Since 2010 he has been a board member of the Sustainable Preservation Initiative (SPI), an organization that uses market forces to create economic incentives for local communities to preserve archaeological sites. In Peru, he has also served in multiple ways as a policy consultant to the *Ministerio de Cultura*. In brief, Charles Stanish legacy is not only imprinted in his significant intellectual contribution to our understanding of ancient Andean civilizations, but also his continued efforts to support generations of emerging local and international scholars and his effective attempts for bringing the cause of archaeology to the general public and the importance of its preservation for future generations.

Star Carr, Archaeology of

Chantal Conneller
Archaeology, University of Manchester, SAHC, Manchester, UK

Introduction

Star Carr is an Early Mesolithic site, dating to c. 9000–8500 BCE. The site is located in the Vale of Pickering, North Yorkshire, UK, near to the coastal town of Scarborough (Fig. 1). During the early Holocene, a large body of water, known as Lake Flixton, was situated at the eastern end of the Vale of Pickering. Star Carr was located on the western shore of this lake. The lake gradually infilled with peat, resulting in excellent preservation of organic remains.

Definition

Star Carr has dominated understandings of the British Mesolithic. This is partly due to the wide variety of organic finds recovered from this waterlogged site, but also due to the influence and interpretation of the original excavator, Grahame Clark. The site has been reanalyzed numerous times, with interpretations varying from a base camp, to a hunting camp, to a ritual site. In addition to Clark's excavations (1949–1951),

Star Carr, Archaeology of, Fig. 1 Location of the site. (Image: Barry Taylor)

fieldwork has been undertaken at the site in 1985 and 1989, and more recently between 2004 and 2011. These new excavations uncovered a large timber platform and a small dwelling structure.

Key Issues/Current Debates/Future Directions/Examples

The discovery of Star Carr was due to the exemplary work of a local archaeologist, John Moore, who had been surveying the Vale of Pickering for prehistoric flints since 1947. Star Carr was Moore's site 4, discovered when flint and bone was seen eroding from the edge of a drainage ditch. Moore sent some of the flints he had recovered to Grahame Clark at Cambridge (Clark 1954). Since the late 1930s, Clark had been dissatisfied with the sort of culture-history accounts he himself had undertaken for his Ph.D. Influenced by Scandinavian archaeology which had a long-standing history of interdisciplinary collaboration with the natural sciences, Clark sought a waterlogged site on which to test his new economic theories. Star Carr seemed the ideal candidate.

Clark spent three summer seasons between 1949 and 1951 at Star Carr. While Moore's excavations next to the drainage ditch revealed an extremely dense scatter of lithic material in the dryland area of the site, Clark focused on the wetland deposits because he was predominantly interested in the recovery of organic material (Fig. 2). A density of 36 pieces of flint per square

Star Carr, Archaeology of, Fig. 2 Excavations at Star Carr. (Image: Barry Taylor)

yard was taken to delimit the limits of the occupied area, making a settlement 18 × 18 m in extent (Clark 1954). Using these criteria, Clark believed he had excavated the entire site and his subsequent interpretations were predicated on this supposition.

The excavation yielded an extremely broad range of material culture, while the waterlogged deposits, as Clark had hoped, produced numerous organic artifacts. Particularly impressive were 21 antler frontlets. These consisted of trimmed and attenuated red deer antlers, still attached to part of the skull. The interior of the skull had been smoothed, and two holes perforated, presumably to facilitate their use as headgear. Using ethnographic analogy, Clark suggested these could either be interpreted as hunting aids, or as costumes in ritual dances. In addition to the frontlets, stone, bone and tooth beads, elk antler mattocks, bone scrapers and bodkins and 191 barbed antler points were found. To give an indication of how significant these finds were, previously only six barbed points had been known from the whole of Britain. Also recovered were more than a hundred grooved antler blanks, presumably intermediate stages in the manufacture of barbed points. Also present was an accumulation of wood, which Clark interpreted as an "occupation platform."

In addition to the worked wood, bone, and antler, faunal remains revealed that a wide variety of animals had been exploited: red deer, roe deer, elk, pig, and aurochs; also smaller creatures – hedgehog, hare, and beaver; a number of fur-bearing carnivores – pine marten, fox, dog, badger, and bear; and a great variety of different birds – crane, stork, red breasted mergaster, red throated diver, great crested grebe, little grebe, lapwing, buzzard, and duck. No fish bones were recovered. Pollen analysis revealed that the lake was surrounded by woodland of birch and pine, with willows by the lake edge. The lake itself was fringed with reedswamp, while waterlillies grew in the open water (Clark 1954).

The original site report (Clark 1954) sealed Star Carr's reputation. Clark interpreted Star Carr as a seasonal site, occupied by not more than four or five families for periods of midwinter and spring and abandoned in the summer. He inferred the presence of men by the recovery of hunting equipment, and women (and thus children), on the basis of analogy with Eskimo groups, from skin working equipment. Particularly important for the future directions of archaeological thought were Clark's considerations of seasonality and subsistence. He placed considerable emphasis on the seasonality data (Clark 1972), which Frazer and King inferred from the antlers of red and roe deer and elk to indicate winter occupation. Clark suggested the site had been occupied at least twice, on the basis of the observation that some charcoal spreads were separated by organic mud and also on vertical patterning in the distribution of barbed point types. The food remains would, it was estimated, have been sufficient to feed the occupants for 6 1/4 years; Clark, thus envisioned repeated visits at particular seasons over a period of years.

Although the site of Star Carr has subsequently undergone many revisions and reinterpretations, Clark's investigations remain an impressively vivid picture of the way of life of a group of Mesolithic hunter-gatherers. As an example of what can be achieved by asking new questions and examining new classes of data, they seemed to call into question the value of earlier excavations.

Two decades later, Clark returned to the Star Carr data in order to expand his interpretation of the site (Clark 1972). Influenced by the concept of the ecosystem, he undertook a site catchment analysis of Star Carr, listing the available resources during the supposed winter stay and relating the number of red deer in this territory to the calorific requirements of a human group and thus deducing the necessary level of the annual cull. Clark attempted to reconstruct the whole settlement system by suggesting, on the basis of the migration patterns of red deer, that human groups had a similar upland/summer, lowland/winter pattern as their prey and that the people who wintered at Star Carr spent their summers hunting deer on the North York Moors.

Following Clark's retirement in 1973, the site was the subject of numerous reinterpretations during the late 1970s and 1980s. Over these, the shadow of Clark's work loomed large, as subsequent commentators focused on similar concerns, namely, seasonality, site function, and the relationship of Star Carr to the surrounding environment.

Caulfield (1978), in an early review, made the point that the red deer MNI indicated by antlers substantially exceeds the MNI represented by postcranial remains. This suggests that, because of their use as raw material, red deer antlers were collected and cached, and thus should not be used to indicate the season of inhabitation. More recent authors have pointed out that though Star Carr was originally interpreted as a site of winter occupation, substantial evidence exists for a human presence at other times of the year. Jacobi (1978) pointed to the presence of newborn elk and roe deer, which were likely to have been killed in May or June and of unshed roe deer antlers, a feature habitually used to indicate summer seasonality in southern Scandinavia. Grigson (1981) noted the presence of migratory birds which probably visited the area between May and June. The macrobotanical evidence reveals burnt reed shoots and aspen catkins which would have grown between March and June (Mellars and Dark 1998).

In their classic study of the site, Legge and Rowley-Conwy (1988) analyzed tooth-wear to assess seasonality of occupation. They found a

clear pattern in the roe deer age structure, with all ageable animals appearing to have been killed in May or June, when the youngest animals were about one year old. The pattern among the other animals appears slightly more ambiguous, though Legge and Rowley-Conwy believe none are incompatible with an occupation lasting between May and September, or if an elk mandible is disregarded, between mid-May and the end of June. More recent work by Carter (1997, 1998) based on radiographs of red and roe deer tooth development suggests winter occupation, a return, after half a century to Clark's thesis. It should be noted though that these interpretations follow Clark in attempting to pin down a minimum season of occupation into which all evidence can be fitted; the evidence as it stands could equally encompass visits at a number of different seasons of the year, or even year round occupation.

Site function has equally been an area of some controversy. Some commentators have followed Clark in interpreting the site as a residential base camp (Pitts 1979; Price 1982). Others have suggested more specialist use as a camp for tanning hides (Pitts 1979), a butchery camp (Caulfield 1978), or as a kill site (Andresen et al. 1981). The main support for the interpretation of the site as a base camp is the rich material inventory and evidence of varied activities; the main evidence against is the faunal assemblage, which, with an emphasis on scapulae, mandibles, and lower limb bones does not suggest the sort of prime cuts of meat expected for a base camp. Legge and Rowley-Conwy (1988) compared the faunal assemblage with those recorded by Binford (1978) during his ethnoarchaeological work with the Nunamiut. They found closest similarity between Star Carr and a Nunamiut hunting camp. A hunting camp is a location where faunal remains are brought following minimal processing at the kill site. At the hunting camp more extensive processing of carcasses is carried out and the prime cuts and joints of meat removed to be consumed at the residential site.

While the faunal assemblage is undoubtedly unusual for a base camp, recent excavations at the site and the oral histories of site excavators indicate that Clark was extremely selective in his recovery of faunal remains. Only the best preserved pieces that were identifiable to species were retained. As a result, not too much should be read into the patterns of faunal representation. As many authors have commented (Jacobi 1978; Pitts 1979; Price 1982; Mellars and Dark 1998), attempts to find a single function or a single seasonality of occupation for such a large and complex site are doomed to failure.

In 1985 and 1989, small-scale excavations were undertaken at the site (Fig. 2). The 1985 trench was excavated by Tim Schadla-Hall and the Vale of Pickering Research Trust in order to collect environmental samples. Because it was believed that Star Carr had been excavated in its entirety, artifactual material was unexpected. However lithics, fauna, and a single barbed point were recovered. Most significant was the discovery of a platform of hewn aspen timbers. These were split timbers, lain parallel and perpendicular to the shore. Schadla-Hall's trench was extended in 1989 by Paul Mellars and a series of small testpits were excavated in the dryland area of the site; all produced lithic material, indicating the site was even larger than Clark had envisaged (Mellars and Dark 1998).

In addition to the discovery of the timber platform, the main achievement of the 1980s work came from Petra Dark's program of environmental work that accompanied it. As well as refining knowledge of the vegetation sequence, Dark used close interval radiocarbon dating of charcoal from her cores to elucidate the periodicity of occupation. She suggested, assuming macrocharcoal as a proxy of human activity, that the site was visited for a period of around 80 years, followed by a gap of around 100 years, when occupation was rare, followed by a period of rather more intermittent occupation lasting around 150 years (Mellars and Dark 1998). These findings further highlight the complexity of the site and the problems associated with a single monolithic interpretation of the activity that generated it.

Further light has been thrown on Star Carr as a result of a long-term survey of the shore of palaeolake Flixton by Tim Schadla-Hall between 1976 and 2005. In addition to the reconstruction of the palaeotopography through auger survey,

2 × 2 m testpits were excavated around the shore of the lake at 15 m intervals. This program has revealed numerous additional Mesolithic sites, and a greater understanding of the local context of Star Carr (Connellier and Schadla-Hall 2003). What is clear from this work is that Star Carr is unique in its local landscape. No other site has the same range of material culture. Clark recovered 191 barbed points at Star Carr; only two additional examples have been recovered from sites elsewhere in the Vale of Pickering, one from Moore's site Flixton 1 and one from Schadla-Hall's site, No Name Hill. No further beads or antler frontlets have been found.

Star Carr thus seems to represent a special place within the landscape of the Vale of Pickering. The site appears to have been a focus for the deposition of animal remains in the shallow waters of the lake edge (Connellier and Schadla-Hall 2003). The respectful, patterned deposition of animal remains can be witnessed among other early Mesolithic groups (e.g., Hansen 2003) and among contemporary hunter-gatherer groups, where it is seen as essential in order to ensure that animals continue to give themselves up to the hunter (e.g., Jordan 2003). At Star Carr, these actions appear most focused on the deposition of red deer antler, suggesting both that red deer was the most spiritually important animal and that the antlers (or perhaps the head more generally) were considered to represent the soul or essence of the deer (Connellier 2004).

In 2004, excavations led by Chantal Conneller, Nicky Milner, and Barry Taylor recommenced at Star Carr (Fig. 2). The first large-scale excavations of the dry land area of the site have revealed a small dwelling structure, consisting of a 2.5-m pit surrounded by a ring of posts 3.5 m in diameter. This structure is surrounded by dense scatters of lithic material and animal bone, indicating a wide range of activities were undertaken on the dry land. Furthermore, fieldwalking and testpitting indicate that a continuous spread of lithic material extends for c250 m. In the wetland area of the site, the wooden platform glimpsed in the 1980s excavations has been found to extend for at least 20 m along the lake edge, suggesting the sort of communal endeavor more commonly associated with Neolithic communities. However, the recent excavations have also revealed that Star Carr is under threat. Recent agricultural drainage has resulted in considerable peat shrinkage. Oxidation of the upper deposits, combined with a seasonally fluctuating water table, has concentrated highly acidic sulfates at the level of the wetland organic artifacts (Boreham et al. 2011). As a result, almost all the bone and antler has entirely decayed, while worked wood is now relatively poorly preserved. Though Star Carr is still yielding new information, in a relatively short period of time, the organic material that made it so famous will be lost forever.

Star Carr: Environmental Archaeology

Barry Taylor
Department of Archaeology, University of York, York, UK

State of Knowledge and Current Debates

Introduction

Since its discovery in the late 1940s, Star Carr has remained one of the most famous, and perhaps most important, early Mesolithic sites in Britain. The wealth of archaeological material, including well-preserved organic remains, recorded at the site has revolutionized our understanding of the period. Analysis of the artifact assemblages has led to a new understanding of technological processes, such as antler working (Clark 1954; Elliot and Milner 2010), depositional practices (Chatterton 2003), and even the way Mesolithic people may have perceived and understood their world (Conneller 2004). The discovery of large structures, such as buildings and timber trackways, has also challenged traditional views of early Mesolithic society (Conneller et al. 2012). However, the importance of Star Carr also lies in the long tradition of paleoenvironmental research that has been carried out at the site. From the first excavations in 1949 to the current program of fieldwork, paleoenvironmental analysis has been undertaken as an integral component of the archaeological investigations. As well as describing the nature of the environments that formed at Star Carr, this work has helped to provide a chronology for the human occupation of the site, detected evidence for the deliberate management of plant communities, and described the way in which people responded to changes in the local environment. The result is a detailed record of how early prehistoric hunter-gatherers interacted with the world around them.

Background

Star Carr is an early Mesolithic wetland site located in the eastern Vale of Pickering (North Yorkshire, UK), a low-lying valley separating the uplands of the North York Moors and the Yorkshire Wolds (Fig. 1a). During the time the site was occupied (c. 9000–c. 8600 cal BCE), it lay on the shores of a large lake (the paleo-Lake Flixton) (Fig. 1b). By c. 6000 cal BCE, the lake had in-filled with deposits of marl, lake mud, and peat, while peat-forming wetlands had expanded across the dry ground, burying the site and much of the surrounding landscape. This has helped to preserve a range of organic materials, including artifacts made from bone, wood, and antler, faunal remains, and plants and insects, that have provided a wealth of information on the lives of the people who lived at the site.

Star Carr: Environmental Archaeology, Fig. 1 (**a**) Location of Star Carr and the paleo-Lake Flixton in relation to Britain and (**b**) the relationship between Star Carr and other early Mesolithic sites around the paleo-Lake Flixton

Evidence for Mesolithic activity at Star Carr was first recorded in the late 1940s by John Moore, but the site came to international attention through the excavations carried out by Grahame Clark between 1949 and 1951 (Clark 1954). For Clark, the importance of wetland sites to the understanding of the Mesolithic had been demonstrated by excavations in southern Scandinavia

(such as Mullerup and Holmegård) and northern Germany (particularly Duvensee). The excavators of these sites had recorded a wealth of material culture made from bone, antler, and wood and had employed relatively new paleoenvironmental techniques, such as pollen analysis, to reconstruct the environmental conditions contemporary with the periods of occupation. Lamenting the absence of such sites in Britain and the lack of information they provided, Clark argued that it was necessary to "*. . . excavate in water-logged deposits*, *either in a bog settlement or immediately contiguous to a settlement on dry land*, *since here alone were the physical conditions necessary for the survival of a broad range of organic materials. . .*" (Clark 1954: xxi).

Clark's involvement with the Fenland Research Committee (FRC) in the 1930s had also shown how wetland sites could provide entirely new forms of evidence for past societies through the integration of archaeological and paleoenvironmental studies. The careful, systematic excavation of sites such as Peacock's Farm (Cambridgeshire) had allowed archaeological material to be related directly to the analysis of peat and other wetland sediments, pollen, and plant macrofossils. As well as providing information on the ecological setting of the sites, this also allowed archaeologists to consider how changes to the environment had affected patterns of human activity and how prehistoric communities had shaped and manipulated the local vegetation.

The preservation of pollen was particularly important as it provided a means to date sites by relating them to the known succession of vegetation that had developed across northern Europe. Such work had already been undertaken in Scandinavia, where a relative chronology for many of the Maglemosian sites, such as Mullerup, Svædborg, and Holmegård, had been established through the pioneering work of Knud Jessen, Tage Nilsson, and Johs Iverson (e.g., Nilsson 1947). By the late 1930s, Harry Godwin had established a comparable record of British vegetation and, with his wife Mary, had shown that pollen stratigraphy could be used to date artifacts in relation to the well-documented sites in Denmark and Sweden (Godwin and Godwin 1933). In the absence of direct forms of dating, this provided Clark with a method to relate artifact assemblages from Britain with those from continental Europe on the basis of chronology rather than the less reliable methods of typology.

Research into the environmental history of the lake had already begun several years before Clark's first excavations at Star Carr. During the mid-1940s, John Moore had started to record the sedimentary sequence within the basin, successfully identifying the presence of the paleo-lake (Moore 1951), and Harry Godwin had recorded a pollen profile from the area in 1948 (Clark 1954). However, Clark's work was at an altogether different scale, combining the techniques of archaeological and paleoenvironmental research to create a detailed record of the human occupation of the site. In this, Clark was heavily influenced by his work on the FRC, resuming his collaboration with Harry Godwin and engaging a range of other specialists from the Subdepartment of Quaternary Research at the University of Cambridge as well as individuals from numerous other institutions. He was also supported by several members of the zoology department at the British Museum, particularly Francis Fraser and Judith King who undertook the analysis of the faunal remains. This truly interdisciplinary study set a new standard for Mesolithic archaeology and began an era of well-integrated research that continues to this day.

A History of Environmental Research

Clark, Godwin, and Walker 1949–1951

From the summer of 1949, Clark undertook three seasons of fieldwork at Star Carr, excavating a series of long trenches (referred to as cuttings), through the sediments that had formed at the edge of the lake (Clark 1954) (Fig. 2). During the course of these excavations, Clark recorded an incredible assemblage of bone and antler artifacts, as well as worked flint, antler-working waste, animal bone, and antler. Much of this material was associated with a deposit of largely unworked "birchwood," which Clark suggested had been deliberately laid down to form a stable surface, upon which the inhabitants of the site had lived (Clark 1954: 9).

Star Carr: Environmental Archaeology, Fig. 2 The main areas of excavation and the environmental sampling points at Star Carr (excavated areas are colored *white*)

While Clark undertook the excavations, Godwin and his student Donald Walker set about establishing the environmental history of the site through the analysis of the peat and lake sediments exposed in the trenches and the pollen and plant macrofossils that had been preserved within them (Clark 1954: 56–61). By relating the artifacts recorded by Clark to the site's stratigraphy, they were able to place the evidence for human activity within the environmental sequence and establish the ecological setting of the site during the time it was occupied (Clark 1954: 58) (Fig. 3). A series of cores were also taken through the sediments beyond the extent of the excavations, and the results were brought together to map the spatial extents of the environments that were contemporary with the occupation of the site (Clark 1954: 58).

The results of this work not only established the ecological context of the human inhabitation of Star Carr but also provided information on the site's economy and the timing and frequency of occupation. The paleoenvironmental analysis indicated that activity had taken place within an area of reedswamp that had formed at the edge of the lake, with aquatic vegetation growing in the deeper water and a wood of birch, willow, and aspen growing on the drier ground at the shore (Clark 1954). Although there was no evidence for deliberate management of the local vegetation (Clark 1954: 67), Clark suggested that at least some of the plant species present at the site may have been exploited for food, drawing parallels with other sites where plant remains had been recorded from domestic contexts (Clark 1954: 13–15). Godwin and Walker also noted that reeds had been able to grow within the main areas of activity (Clark 1954: 58), suggesting that the site had been uninhabited during the spring months (Clark 1954: 67).

As well as establishing the character of the environment at the site, Clark used the results of

Star Carr: Environmental Archaeology, Fig. 3 The peat stratigraphy recorded by Godwin and Walker and its relationship to the archaeological evidence for human activity (After Clark 1954: 59 Fig. 27a)

the pollen analysis to relate Star Carr chronologically to the Maglemosian sites of Northern Europe. Typological similarities had already been noted between these and sites in England on the basis of flint technologies, while Mary and Harry Godwin had used comparative pollen analysis to show that two antler harpoon points discovered in North Yorkshire were contemporary with Maglemosian examples from Denmark (Godwin and Godwin 1933). A comparison of the pollen data from Star Carr, however, showed that the site was earlier than many of the Danish sites, a finding that appeared to be supported by differences in both flint and antler-working techniques (Clark 1954: 179–180). This led Clark to conclude that Star Carr represented an earlier form of the Maglemosian "culture" that was still influenced by traits from the Upper Paleolithic (Clark 1954: 191).

In addition to the evidence from the ecological studies, Clark also made good use of the faunal remains that he had recorded from the excavations and that had been analyzed by Fraser and King. They identified the species of animals that were present and established the minimum number of individuals that were represented within the assemblage. On the basis of this analysis, they showed that the inhabitants of Star Carr had hunted a wide range of different animals but that red deer were the most important to the economy of the site. By calculating the approximate amount of meat produced by butchering these animals and estimating the dietary requirement of a postglacial hunter-gatherer, Clark also estimated the total length of time the site had been in use, which he placed at six and a quarter years (Clark 1954: 14–15).

However, by far the most significant (and highly debated) use of the faunal assemblage was in establishing the seasonality of the site. Based on the time of year that red deer are known to lose their antlers, Fraser and King argued that the unshed material must have come from animals that were hunted between October and April (Clark 1954: 93), while shed antler could only have been collected in April (Clark 1954). From this it was argued that the site was occupied during the winter and spring months (Clark 1954) and that the inhabitants had moved to other locations during the summer. While this idea of seasonal mobility was largely implicit in Clark's original publications, he developed the idea further in his subsequent reanalysis of the site (Clark 1972). Here, he argued that the occupants of Star Carr had moved annually between lowland and upland locations as they followed migrating herds of red deer, an argument that was based upon behavioral studies of modern animal populations.

The Vale of Pickering Research Trust: 1985

In 1985 a new program of work was begun at the site, under the auspices of the Vale of Pickering Research Trust (Cloutman and Smith 1988). The Trust had been formed following the successful completion of the Seamer Carr Project, which had carried out extensive archaeological and paleoenvironmental surveys of the Mesolithic landscape along the northwest shore of Lake Flixton (Cloutman 1988a, b; Milner et al. 2011; Lane and Schadla-Hall Forthcoming). Using the skills and experiences that had been gained from this, the Trust aimed to expand upon the work of Godwin and Walker by creating a more detailed pollen record at Star Carr (Mellars and Dark 1998: 14).

Although the work of Godwin and Walker was exemplary for its time, the scope of their interpretations was limited by some of the approaches they adopted. In particular, the pollen analysis, which had only been carried out on a single profile and recorded at a very low resolution, was unlikely to detect subtle or gradual changes to the local vegetation. This, combined with the lack of radiocarbon dates from the environmental sequence, made it impossible to determine the timing and nature of environmental change at the site. However, advances in the techniques of paleoecology, and particularly palynology, and the wider availability of radiocarbon dating provided the opportunity to establish a more comprehensive record of the environments at Star Carr.

Much of this work was carried out by Edward Cloutman, who had undertaken the surveys at Seamer Carr, and was supervised by Alan Smith, who had formerly worked with Godwin at the Subdepartment of Quaternary Research. Based on work they had carried out at other sites, Cloutman and Smith argued that pollen profiles from lake-edge deposits were heavily influenced by the local vegetation and provided an accurate record of the environment that had formed close to the point where the samples were obtained (Cloutman and Smith 1988: 43 & 53). As such, a series of pollen profiles recorded at intervals from the lake edge and into the basin would document the spatial extents of the wetland vegetation and its development through time (Cloutman and Smith 1988). To achieve this, two new trenches (VP85A & B) were excavated through the lake-edge deposits, approximately 25 m to the east of the area investigated by Clark, and a series of pollen profiles were recorded from points along their length (Cloutman and Smith 1988: 38) (Fig. 2). These were correlated using common horizons within the pollen and peat stratigraphies (Cloutman and Smith 1988: 48–51), and an absolute chronology was established by radiocarbon dating.

In contrast to the work carried out by Godwin and Walker, Cloutman and Smith showed that the lake-edge environments had developed throughout the time that Star Carr was occupied. The reedswamp, which had traditionally been associated with the occupation of the site, had expanded into the deeper parts of the lake during the first few centuries of the Mesolithic, and a drier, fern-dominated fen had developed closer to the shore (Cloutman and Smith 1988: 52). Based on the relationship between the pollen and peat stratigraphies and a small assemblage of artifacts recorded during the excavations, Cloutman and Smith argued that it was in this environment that activity had taken place. The pollen analysis also detected an area of wetter ground that had formed around the time the site was first inhabited. This appeared to have been stabilized by the construction of a timber platform, the remains of which had been recorded during the excavation of the trench (Cloutman and Smith 1988).

However, while Cloutman and Smith provided a very detailed record of the changing environments at Star Carr, the chronology established by the radiocarbon dates was problematic. To begin with, the samples taken from the base of the profiles predated the start of the Holocene, leading Cloutman to suggest that older material had become reworked and incorporated into the basal sediments (Cloutman and Smith 1988: 45). Furthermore, many of the dates clustered at c. 9500 BP, which Mellars, drawing on the results of recent dendrochronological work, subsequently argued, were the result of a radiocarbon plateau (Mellars 1990). This, along with the large error range of many of the determinations and the relatively low sample interval of the pollen analysis, made it difficult to establish the date and

timing of environmental change in certain parts of the sequence (Cloutman and Smith 1988: 840).

Paul Mellars and Petra Dark (Née Day): 1989–1992

It was partly in response to these concerns that a new program of research was undertaken at the site in the 1990s by Paul Mellars and Petra Dark, again with the support of the VPRT (Mellars and Dark 1998). As well as dealing with the issues of chronology, Dark also sought to refine the environmental record for the site through high-resolution pollen analysis (Mellars and Dark 1998: 112). This, she argued, had the potential to detect discrete changes to the local vegetation, which, if related to human action, could be used to establish the duration and season of occupation, as well as providing evidence for the exploitation of the local flora (Mellars and Dark 1998).

Between 1989 and 1992, three new pollen profiles were recorded from samples taken from Trench VP85A, while a fourth profile was recorded just to the south of Clark's excavations (Cutting II) (Fig. 2). As well as the analysis of pollen, micro- and macro-charcoal were recorded from all of the profiles to identify episodes of localized burning and relate this to evidence for vegetation disturbance (Mellars and Dark 1998: 115–6). A new radiocarbon chronology was also established from AMS dates obtained on terrestrial macrofossils (Mellars and Dark 1998: 117), and "wiggle matching" and Bayesian analysis were used to overcome the difficulties caused by the plateau in the calibration curve (Mellars and Dark 1998: 119–121).

Dark's research broadly supported the environmental sequence that had been outlined in previous work at the site, documenting the expansion of fen and carr across the former lake edge. However, Dark also argued that some of the changes to the wetland vegetation recorded by Cloutman and Smith were unlikely to be the result of natural plant succession (Mellars and Dark 1998: 155) but had, instead, resulted from the deliberate clearance of the lake-edge flora. The most significant of these was a rapid decline in grass (Poaceae) pollen, much of which was thought to have derived from *Phragmites* reeds, which corresponded with an increase in micro- and macro-charcoal (Mellars and Dark 1998: 130). This, Dark argued, had been caused by the deliberate clearance of the reedbeds by fire (Mellars and Dark 1998). A similar decline in grass pollen and a corresponding increase in charcoal was recorded from the profile to the south of Clark's Cutting II, suggesting that the reedswamp in this area was also cleared at around the same time (Mellars and Dark 1998: 158) and a second phase of burning occurred approximately a century later in both parts of the site (Mellars and Dark 1998: 157).

Dark also established the time of year that the first phase of burning occurred, based on the presence of carbonized fruits, bud scales, and juvenile reed tissue within the deposits, and used this to infer the season of occupation at the site (Dark 2004). She argued that the *minimum* period during which the burning took place was between late April and the end of August but that it could have occurred as early as late winter (February) and as late as the end of September (Dark 2004: 41–2). However, Dark noted that occupation did not have to be continuous and that the site may have been revisited at different times of the year. She also pointed out that plant remains would not be able to detect evidence for burning during the winter, as they do not produce identifiable structures, such as fruits or bud scales at this time of the year (Dark 2004: 42).

Both the evidence for burning and the revised dating of the environmental sequence were also used to establish a chronology for human activity at Star Carr. First, Paul Mellars compared the vertical distribution of the artifacts in VP85A with the dated peat stratigraphy, which suggested that the archaeological assemblage had been deposited over a period from c. 8700 to c. 8400 cal BCE (Mellars and Dark 1998: 210). Subsequently, Dark used the deliberate burning of the local vegetation to establish a more detailed chronology of the site (Dark et al. 2006). Based on the dating of the charcoal record, she argued that the first phase of burning began c. 8970 cal BCE, lasted for approximately 80 years (slightly longer at Clark's site), and was broadly synchronous across the site (Mellars and

Star Carr: Environmental Archaeology, Fig. 4 Concentrations of charcoal and the vertical distribution of artifacts in Trench VP85A (After Dark et al. 2006: 189)

Dark 1998: 159; Dark et al. 2006: 191). In both of the trenches, it also coincided stratigraphically with the larger part of the artifact assemblage, leading Dark et al. to suggest that it represented the main period of occupation (Dark et al. 2006: 191) (Fig. 4). A second phase of burning occurred in the area around VP85A from c. 8790 cal BCE, lasting 130 years, while a further episode occurred approximately a century later in the area covered by Clark's excavations. As these both corresponded with smaller quantities of artifacts, Dark et al. suggested that there had been "a shift in the main focus of activity to other parts of the lake edge zone" (Dark et al. 2006: 198). Crucially, direct dating of the faunal assemblage and material culture has broadly supported these interpretations (Dark et al. 2006; Conneller et al. 2009), indicating that the charcoal record is a reasonable proxy for human activity at the site.

Reinterpretations and Debates

In the decades following the publication of his excavations at Star Carr, Clark's interpretation of the site remained largely unchallenged. However, from the late 1970s, several key points of his work became the subject of extensive critique: the interpretation of the faunal assemblage and what this said about the time of year the site was occupied, and the seasonal basis for mobility and the depositional context of the artifact assemblage. In both cases, the debates surrounding these issues led to new interpretations of the function of the site and its relationship to the wider pattern of activity within the surrounding landscape.

Changing Interpretations of the Faunal Assemblage

Species Representation and the Season of Occupation

The analysis of the faunal assemblage from Star Carr formed the basis for Clark's interpretation of the site as a winter base camp, inhabited by seasonally mobile hunters following herds of migrating red deer. However, in the late 1970s, Seamus Caulfield (1978) argued that the original analysis and the conclusions drawn from it were fundamentally flawed. The central point of his argument was that Fraser and King had included the shed and unshed red deer antler when calculating the number of animals represented in the assemblage and the time of year they had been killed (Caulfield 1978: 15). However, a reassessment of the data showed that the antler was overrepresented in comparison to the postcranial elements of the skeleton, suggesting that it had been brought onto the site, possibly for use as raw material (Caulfield 1978: 18). As such, its inclusion by Fraser and King had over emphasized the importance of red deer and had produced a potentially inaccurate record of the time of year the site was occupied.

However, subsequent attempts to establish the seasonality of Star Carr based on the existing data met with mixed success. Discounting the red deer

from the assemblage, Roger Jacobi (1978) argued that the faunal evidence indicated that activity had extended into the early summer. In contrast, Mike Pitts (1979) and John Andersen et al. (1981) used a combination of the botanical and the faunal evidence to argue that there was no single season of activity and that the site had either been occupied all year round (Pitts 1979: 33) or had been visited at different times of the year (Andresen et al. 1981). Based in part on the reassessment of the faunal assemblage, Andersen et al. also suggested that Star Carr had acted as a temporary hunting site, where animals had been killed and subsequently butchered, rather than an area of settlement (Andresen et al. 1981).

In the face of these varied and contradictory readings of the data, a comprehensive reanalysis of the faunal assemblage was carried out by Tony Legge and Peter Rowley-Conwy (1988). Accepting that the adult red deer crania with unshed antlers were an unreliable indicator of seasonality, they focused instead on the age-at-death profile of the younger animals based on tooth eruption data. This showed that young roe deer and, where age could be established, young red deer were being killed in the summer (Legge and Rowley-Conwy 1988: 25 & 38), while the presence of adult red deer crania that had shed their antler indicated a kill around April or May (Rowley-Conwy 1988: 30). Furthermore, only one individual (a juvenile elk) showed conclusive evidence for a kill later in the year (Rowley-Conwy 1988: 31–2), leading Legge and Rowley-Conwy to conclude that a summer occupation was most likely (Rowley-Conwy 1988: 94). These conclusions have since been refined through work carried out by Richard Carter who used radiographs of juvenile roe and red deer jaws to establish a more precise season of death. This showed that the young roe deer were killed slightly earlier in the year (Carter 1997 cited in Mellars and Dark 1998: 216), while at least one juvenile red deer was probably killed in the winter (Carter 1998: 855).

Drawing together the work of Carter, Legge and Rowley-Conwy, and Dark, Mellars argued that Star Carr was probably occupied between late spring (April/March) and early summer (June or early July) (Mellars and Dark 1998: 216). However, the ability to draw such conclusions from faunal and botanical data has been criticized by a number of researchers. Nicky Milner, for example, has argued that inferring the season of occupation on the basis of faunal data is fraught with difficulties, noting in particular that seasonally diagnostic material can be imported onto a site (as was the case with the red deer antlers) and that some activities leave no evidence of when they were undertaken (Milner 2005a: 34). Furthermore, indicators of activity at different times of the year are often assumed to form part of the same phase of occupation, rather than separate episodes of activity carried out on separate visits to the site (Milner 2005b: 58). As such, they tend to reduce variable and complex behavior into a single seasonal event (Milner 2005b).

With this in mind, the data from Star Carr could easily reflect multiple visits to the site at different times of the year, especially if the apparently anomalous evidence for the hunting of animals in autumn and winter that was recorded by both Legge and Rowley-Conwy (1988) and Carter (1998) is considered. This point has also been made by Dark, who has stated that while the evidence for burning at Star Carr spanned several months of the year, occupation at the site may have been more intermittent and that the data could reflect a series of discrete events (Dark 2004: 42). It is also important to note that none of the seasonally diagnostic material has been dated and that the evidence for activities in different months may not be contemporary. Overall, the evidence for a single season of occupation is far from unambiguous, and it remains possible that the site was visited on multiple occasions throughout much, if not all, of the year.

The Economic and Seasonal Basis for Mobility

Clark's model of a seasonal pattern of upland-lowland migration has also been critiqued, most notably by Legge and Rowley-Conwy (1988). They argued that the studies of red deer behavior that Clark drew upon were not applicable to Star Carr as they were based on open rather than wooded landscapes (Legge and Rowley-Conwy

1988: 13). Furthermore, they noted that deer in wooded environments do not migrate over long distances and would not necessarily have been absent from the vicinity of Star Carr during the summer season (Legge and Rowley-Conwy 1988). Similarly, they argued that the other animals that were being hunted and killed at Star Carr either were nonmigratory or would have been present in the area during the time of year the site was occupied (Legge and Rowley-Conwy 1988: 38).

But while the specific details of Clark's argument have been critiqued, the underlying assumption that Star Carr related to a wider pattern of seasonal mobility and resource procurement has persisted. Legge and Rowley-Conwy, for example, suggested contact between Lake Flixton and the nearby coastal areas, stating that these would have provided a range of resources "at seasons complimentary to that in which Star Carr is known to have been occupied" (Legge and Rowley-Conwy 1988: 95). This initially found some support from carbon isotope analysis carried out on the remains of a Mesolithic dog at Seamer Carr (Site K), just 1,200 m to the northeast of Star Carr, which showed evidence for a significant marine component to its diet (Clutton-Brock and Noe-Nygaard 1990) (see Fig. 1b). Arguing that the results could serve as a proxy for the diet of humans (Clutton-Brock and Noe-Nygaard 1990: 649), Clutton-Brock and Noe-Nygaard suggested that the inhabitants of Seamer Carr spent most of their time at the coast and that the sites around Lake Flixton (including Star Carr) represented temporary inland hunting stations (Clutton-Brock and Noe-Nygaard 1990: 650).

However, the veracity of this argument has been questioned on both methodological and interpretive grounds. To begin with, Petra Dark argued that the marine values were the result of carbon from the lake water entering the food chain via animals grazing on aquatic plants (Day 1996), though this has been refuted by Rick Schulting and Mike Richards (2002, 2009). Schulting and Richards (2002) have also questioned whether the diet of a single animal is representative of patterns of human activity spanning several centuries. As they note, visits to the coast may have occurred infrequently and not necessarily as part of a seasonal inland-coastal migration, while the dog itself may have been traded and need not reflect the movement of a human population (Schulting and Richards 2002: 331). These critiques have been supported by a more recent isotopic study on the remains of two dogs from Star Carr, neither of which showed evidence for a marine diet (Schulting and Richards 2009: 502).

Alternative Interpretations of the Faunal Remains

While the interpretation of the faunal assemblage has been dominated by the debates surrounding seasonality, several researchers have focused on the cultural attitudes towards the animals themselves. In particular Pollard (2000), Chatterton (2003), and Conneller (2003, 2004; Conneller and Schadla-Hall 2003) have all suggested that elements of the faunal assemblage and the artifacts made from bone and antler may have been deposited through deliberate acts of disposal that were related to concepts of animal agency. Pollard and Chatterton have separately argued that this involved treating the remains of animals with respect in order to ensure successful hunts in the future (Pollard 2000: 125–6; Chatterton 2003: 78). Conneller has also taken a slightly different view, arguing that the artifacts made from red deer, and particularly the barbed points and the antler frontlets, were used in transformative practices in which aspects of animal identity could be taken on by humans (Conneller and Schadla-Hall 2003: 102–3; Conneller 2004).

The Context of Deposition and Site Function

The depositional context of the material culture recorded by Clark has also been debated, leading to a number of reinterpretations of the forms of activity that the assemblage represents. Clark himself had argued that the artifacts had been deposited into an area of reedswamp that lay at the edge of the lake and represented an area of occupation (Clark 1954: 12). However, since the late 1970s, several archaeologists have argued that the assemblage was actually deposited into standing water, making it an unlikely place for inhabitation (e.g., Price 1982; Chatterton 2003). As a result, the assemblage has been variously

reinterpreted as a dump of material discarded as waste, the remains of specialized craft activity (particularly tanning and antler working), or the results of culturally prescribed acts of deposition and disposal (e.g., Price 1982; Pitts 1979; Chatterton 2003; Conneller 2004). These reinterpretations have themselves been critiqued by Paul Mellars, who has argued strenuously in favor of Clark's original narrative (Mellars and Dark 1998; Mellars 2009).

Unfortunately, Clark's excavation records lack the necessary contextual detail to resolve this debate, and researchers have had to rely upon other, less direct, forms of evidence often leading to contradictory conclusions. Doug Price, for example, cited the preservation of the bone and antler to argue that they were deposited into standing water, while Paul Mellars used the spatial distribution of the flint artifacts to argue for in situ activity in a relatively drier environment (Price 1982; Mellars and Dark 1998: 218–221). Richard Chatterton has pointed out that the deposits from which much of the archaeological material was recorded contained aquatic plant material (Chatterton 2003: 70 citing Clark 1954: 58), though Mellars has countered this, suggesting that this could have been washed in by periodic flooding or represented the waste from plants collected for food (Mellars 2009: 506). Finally, both Chatterton and Mellars have used the paleoenvironmental work carried out by Dark to determine whether the area investigated by Clark would have been beneath or beyond the water level of the early Mesolithic lake (Chatterton 2003: 70; Mellars and Dark 1998: 221; Mellars 2009: 506). Unfortunately, alleged discrepancies in the topographic survey of the site (Mellars 2009: 506) have meant that the two authors came to very different conclusions.

However, recent archaeological and paleoenvironmental research at Star Carr has begun to resolve this issue. Since 2004 a new program of fieldwork has been carried out at the site, which has included the excavation of trenches through the lake-edge deposits and the re-excavation of some of the areas investigated by Clark and the VPRT (Milner et al. 2011; Conneller et al. 2012). This has recorded further evidence for Mesolithic activity, including timber platforms and artifact assemblages, as well as providing an opportunity for new paleoenvironmental investigations. In particular, the analysis of plant macrofossils taken from the section of Clark's Cutting II, VP85A, and several of the new trenches has provided a very detailed picture of the environments that were forming at the site (Hall et al. 2007; Hall 2009; Taylor 2012). By relating this work stratigraphically to the archaeological evidence, it has been possible to develop a precise contextual record of the various episodes of human activity (Taylor 2012).

This work has shown that there was no single context of deposition and that artifacts were deposited into a range of different environments, the nature and extent of which changed during the time the site was inhabited (Taylor 2012: 351; see also Taylor 2011: 78–80). The earliest artifacts were deposited into shallow standing water close to the lake shore, with swamp vegetation growing in situ. However, as the peat began to accumulate, the depth of water at the lake edge became shallower until the area eventually became terrestrialized, and trees and fen plants became established (Taylor 2012: 360). Yet despite the changing nature of these environments, artifacts continued to be deposited across the lake-edge wetlands. In some places, the material appears to have been discarded as waste from nearby areas of craft activity; in others, it may have been deposited more deliberately, while in some parts of the site, the artifacts represent tasks that were being carried out in situ within the wetland environments (Taylor 2012: 351–2). What is more, the nature of activity associated with the wetlands changed as these environments developed. The use of the timber platforms, for example, occurs at a time when the depth of water was becoming shallower and conditions at the lake-edge boggier (Conneller et al. 2012). As the deposits began to form above the level of the lake and the wetlands became more terrestrialized, activities that had formerly taken place on the dry ground, such as antler working, were carried out within the fen itself (Taylor 2007). This explains some of the very contradictory interpretations of the site. Clark and subsequent researchers have treated

Star Carr: Environmental Archaeology, Fig. 5 Location of environmental profiles within the Lake Flixton basin (excluding those recorded by Godwin and Walker). *1* VP85A1–3 and VP85B (Cloutman and Smith 1988) and M1–3 and "Clark's site profile" (Mellars and Dark 1998), *2* deep lake profile (Mellars and Dark 1998), *3* AK87 (Lane and Schadla-Hall Forthcoming), *4* D1 (Cloutman 1988b), *5* K2 and 5 (Cloutman 1988b), *6* M285 (Cloutman 1988b), *7* CV, CVII, and CVIII (Cloutman 1988b), *8* E77 (Cloutman 1988b), *9* NAQ and NAZ (Cummins 2003, Taylor 2011, 2012); *10* NM (Cummins 2003); *11* profile D (Cummins 2003); *12* LAL (Cummins 2003); *13* LAP (Cummins 2003); *14* FS95 (Cummins 2003); *15* PCC (Cummins 2003); *16* Trench F (Taylor 2011, 2012); and *17* core 1(Taylor 2011, 2012)

the faunal and artifactual material as a single assemblage. However, the recent work has shown that the site is, in fact, a palimpsest, reflecting successive phases of activity, taking place in very different environments, and spanning several centuries. It is not, therefore, surprising that studies of the animal bone have been unable to show a single season of occupation nor that the material culture reflects very different forms of activity indicative of different types of environmental conditions. The key to understanding Star Carr is to appreciate the diverse character of activity and its relationship with the changing character of the wetland environments.

Paleoenvironmental Research in the Wider Landscape

Since the late 1940s, paleoenvironmental investigations have also been carried out across much of the basin, documenting the environmental history of the lake and establishing the ecological context of other areas of Mesolithic activity (Fig. 5). As at Star Carr, much of this work has been carried out as part of archaeological investigations, creating a well-integrated record of both the human and environmental histories of the landscape.

The first large-scale investigations were carried out by Godwin and Walker who recorded the stratigraphy of the basin through a series of auger transects and used pollen and plant macrofossils to document the changing character of the wetland and terrestrial vegetation. Their results showed that the lake had formed at the start of the late glacial interstadial but had been colonized by swamp and fen environments during the Mesolithic, leading to the eventual in-filling of the basin (Clark 1954: 61–9). Since the mid-1970s, however, more intensive programs of work have been undertaken, first under the auspices of the Seamer Carr Project and then the VPRT, which have created a far more precise record of both the topography and the vegetational history of the area.

To begin with, large-scale auger surveys have been carried out across the former lake, mapping much of the buried Mesolithic land surface including almost all of the shore, the adjacent terrestrial landscape, and substantial parts of the basin (Cloutman 1988a; Lane and Schadla-Hall Forthcoming). The augering has also recorded the sequence of sediments that formed within the lake, while pollen analysis has been carried out in order to document the changing patterns of vegetation. Perhaps the most intensive program of work was carried out at Seamer Carr by Cloutman, who recorded eight pollen profiles from locations along the shore, within the deeper lake margins and on the terrestrial landscape (Cloutman 1988b). By correlating these on the basis of common horizons within the pollen stratigraphies, Cloutman was able to map the expansion of different wetland environments into the lake as well as documenting changes to the adjacent terrestrial vegetation (Fig. 6). Since then, pollen profiles have been recorded by Jim Innes at Flixton Island (Lane and Schadla-Hall Forthcoming) and by Gaynor Cummins at No Name Hill, Barry's Island, and Flixton School Field (Cummins 2003), establishing the character of the vegetation around each of these sites. Both Cummins (2003) and Dark (Mellars and Dark 1998) have also documented the regional pattern of vegetation through the analysis of pollen from the deepest parts of the basin. More recently plant macrofossil analysis has been carried out at Flixton School House Farm and No Name Hill (Taylor 2011, 2012). At both sites profiles were recorded at intervals from the lake edge into the deeper lake margins and correlated using radiocarbon dates to provide a precise record of the timing of wetland succession (Taylor 2011, 2012).

When brought together, this work has created a very detailed record of the environments that were forming within and around the lake at the time that Star Carr was occupied. The lake itself was over 4.5 km long, with a complex and varied shoreline interspersed with embayments, small promontories, and larger hilly peninsulas (Taylor 2011: 65).

Star Carr: Environmental Archaeology, Fig. 6 The spatial extents of the early Mesolithic wetland environments at Seamer Carr (After Cloutman 1988b: 33 Fig. 7)

Around much of the shore, low hills overlooked the lake, while areas of low-lying ground created small boggy hollows and seasonal ponds (Taylor 2011). By the start of the Mesolithic beds of *Phragmites* reed, sedges and other wetland plants were well established along much of the shore, with floating aquatic plants growing in the deeper water (e.g., Cummins 2003: 281). Along the shore, willow, aspen, and birch were growing at the water's edge, and birch woodland, interspersed with areas of open grassland, covered the surrounding terrestrial landscape (Cummins 2003: 280). As at Star Carr, these environments developed rapidly as the accumulation of sediments caused the lake to become shallower, allowing swamp vegetation to expand into the basin (e.g., Taylor 2011: 76). By c. 8500 cal BCE, the sediments at the lake edge were forming above the level of the lake, and fen plants and trees had begun to colonize the wetlands (Taylor 2011).

These analyses have also helped to show how Mesolithic people engaged with their environment. In a detailed study of the lithic assemblages from sites around the lake, Conneller observed that the assemblages that were recorded from the wetland deposits lacked evidence for in situ knapping and were dominated by flakes and blades (e.g., Conneller and Schadla-Hall 2003: 100). These, she argued, reflected the use of flint at the wetland's edge for tasks that included the cutting of material (Conneller and Schadla-Hall 2003: 100). Macrofossil analysis at one of these sites (No Name Hill) showed that some of the flint had been deposited into reedswamp that was growing in shallow standing water over 5 m from the shore (Taylor 2011: 77). This, it has been argued, showed that people were carrying out tasks *within* the wetlands, possibly including the clearance or collection of reeds for use as food or raw materials (Taylor 2011). Other parts of the flint assemblage, again dominated by flakes and blades, had been deposited in waterlogged sediments that had formed at or close to the shore (Taylor 2011). Although this material may reflect a range of different activities, it is possible that part of the assemblage was deposited while working antler, as several pieces of antler-working waste were recorded nearby (Taylor 2011).

As at Star Carr, there is also evidence that Mesolithic people were deliberately manipulating and managing the wetland vegetation in the wider landscape. High-resolution pollen and charcoal analysis carried out by Cummins has shown that the reed and sedge beds at No Name Hill and Flixton School Field were cleared by burning for prolonged periods and on multiple occasions (Cummins 2003). Although the reason for the burning is debated, the most common argument is that it formed part of an economic strategy that was designed to maintain predictable and reliable resources around the landscape. Regular burning of the reed beds would, for example, increase their biomass and encourage their expansion while at the same time preventing other plants from colonizing the area (e.g., Mellars and Dark 1998: 231; Cummins 2003: 297). This would create large, productive, stands of reeds that could then be exploited for either food or raw materials. Alternatively, it has been argued that the burning of the reeds would promote the growth of young shoots and create openings at the edge of the lake, attracting animals to the area and making them easier to hunt (Cummins 298–9; Mellars and Dark 1998: 231–2).

The environmental work that has taken place around the former lake has also helped to relate Star Carr to the pattern of activity within the surrounding landscape. Cummins, for example, showed that activity at other locations around the lake (No Name Hill and Flixton School Field) was broadly contemporary with Star Carr, based on the dates for the charcoal sequences at each of the sites (Cummins 2003: 292). As at Star Carr, the dating of the charcoal records from these sites also showed that they were occupied (or revisited) for decades at a time (Cummins 2003: 291–2). Similarly, the macrofossil analysis at No Name Hill has shown that activity within the wetlands spanned the period over which these environments changed, with evidence for tool use within the swamp and the later fen and carr (Taylor 2011: 77–8). It also demonstrated that very similar kinds of activity were taking place in the same sorts of environment at the two sites. When seen in this context, it becomes clear

that activity at Star Carr was part of a much broader pattern of occupation that was focused around the shores of the lake.

Conclusions

In the closing sentences of the Star Carr monograph, Clark wrote that his excavations had "opened up rather than closed a field of prehistoric research" (Clark 1954: 191), and it is a testament to the importance of the site that this statement remains true to this day. While Clark's work at Star Carr laid the foundations for Mesolithic archaeology in Britain, the subsequent reinterpretations and the new excavations they inspired not only have refined our knowledge of the site but also have changed the way we understand the period as a whole (Conneller 2003). The issues of seasonality that dominated discussions of the faunal assemblage throughout the 1970s and 1980s have led to more critical debates surrounding the idea of seasonal mobility during the early Mesolithic (e.g., Milner 2005a, b). Furthermore, renewed analyses of the faunal assemblage as well as the material culture from the site have led to altogether new approaches to the study of animals and how they may have been perceived by humans (e.g., Conneller 2004). Similarly, the traditional view of Mesolithic society as consisting of small, highly mobile groups has been challenged by many of the new discoveries at Star Carr: the deliberate manipulation of the environment, the temporally extensive nature of occupation, and the construction of large structural features such as trackways (Conneller et al. 2012). Writing almost 50 years after Clark, Conneller wrote that "to change our understanding of Star Carr is to change our understanding of the British Mesolithic itself" (Conneller 2003: 82). Let us hope that over the next 50 years, Star Carr will continue to challenge our perception of early Mesolithic societies.

Stark, Miriam

Alison Kyra Carter
Department of Anthropology, University of Oregon, Eugene, OR, USA

Basic Biographical Information

Miriam T. Stark is an American Archaeologist and Professor of Anthropology at the University of Hawai'i at Mānoa (Fig. 1). She grew up in East Lansing, Michigan, earning a B.A. in Anthropology and English from the University of Michigan in 1984. From an early age, Stark's mother exposed her to archaeology, signing her up for a 6-week archaeology-themed summer trip to Israel in 1978 where she worked on the site of Tel Afek. In 1982, her study of archaeology began in earnest when she volunteered to work with graduate student Tristine Smart on a field survey in the Hocking Valley, Ohio, and became interested in archaeology as a career. She began pursuing Southwestern archaeology through participation in two field schools in New Mexico in 1983: first with the University of New Mexico/New Mexico State University Field School at Rowe Pueblo (under the direction of Linda Cordell, Fred Plog, and Steadman Upham) and then at Ladder Ranch (under the direction of Margaret Nelson).

She earned her Master's (1987) and Ph.D. (1993) from The University of Arizona, where she wrote her doctoral dissertation on "Pottery Economics: A Kalinga Ethnoarchaeological Study" under the supervision of William Longacre. Following completion of her doctoral degree, she was a Materials Analysis Postdoctoral Fellow in the Conservation Analytical Laboratory at the Smithsonian in Washington, D.C. She joined the Anthropology Department at the University of Hawai'i at Mānoa as an Assistant Professor in 1995 and was promoted to Associate Professor in 2000 and then to Professor in 2006. She currently directs the university's Center for Southeast Asian Studies (2018–2022).

Major Accomplishments

Dr. Stark has worked extensively on political economy in premodern Southeast Asia, beginning with her graduate school studies as a participant in the Kalinga Ethnoarchaeology Project during the 1987–1988 field season. Her Ph.D. research used an ethnoarchaeological case study based in the village of Dalupa, Philippines (Fig. 2), to explore a study on pottery economics including the production, use, and distribution of pottery across a landscape. She has published extensively on

Stark, Miriam, Fig. 1 Photo of Miriam Stark. (Photo provided by Miriam Stark)

Stark, Miriam, Fig. 2 Miriam Stark interviews a Kalinga potter in the village of Dalupa. (Photo provided by Miriam Stark)

this work (e.g., Stark 1991a) as well as related topics such as the archaeology of social boundaries (e.g., Stark 1998) and ceramic ethnoarchaeology (e.g., Stark 2003). Her more recent ceramics research includes a collaborative project aimed at understanding the production and exchange of stoneware ceramics in the Angkorian Empire.

Although her Ph.D. focus was on the Philippines, Dr. Stark maintained an interest in Southwestern archaeology, working as a Research Archaeologist with Desert Archaeology (Tucson, AZ) and as part of the Homol'ovi Research Program (Arizona State Museum). She has also published on Southwestern ceramics (e.g., Stark and Heidke 1998).

Stark has long been concerned with issues related to gender equity in archaeology. She co-authored an examination on "The Status of Women in Archaeology" (Kramer and Stark 1988), and a later publication (Stark 1991b) scrutinized the gender differences between men and women in academic and nonacademic archaeology as part of a research assistantship with Dr. Carol Kramer. Dr. Stark served on the Committee on the Status of Women in Anthropology for the Society for American Archaeology (1992–1997) and for the American Anthropological Association (1997–2000) and continues to speak on these issues at academic conferences.

In 1992 and later in 1994, Dr. Stark worked in mainland Southeast Asia as a participant in the Thailand Archaeometallurgy Project (TAP). In 1996, her attentions shifted to Cambodia where she co-directed the Lower Mekong Archaeological Project (LOMAP) in collaboration with Cambodia's Ministry of Culture and Fine Arts (Fig. 3). This project grew out of an earlier collaboration between the Royal University of Fine Arts in Phnom Penh, the University of Hawai'i, and the East-West Center focused on training and rebuilding the Cambodian archaeology program following Cambodia's Khmer Rouge period (Stark and Heng 2018). Capacity building has been a core component of Dr. Stark's research in Cambodia, with over 80 Cambodian Royal University of Fine Arts students and interns having been trained on her projects between 1995 and 2015.

Stark, Miriam, Fig. 3 Miriam Stark (right) and Cambodian Archaeologist Dr. Piphal Heng (left) undertake field survey in Takeo Province, Cambodia, as part of the LOMAP project. (Photo provided by Miriam Stark)

Nine seasons of excavation, survey, and interdisciplinary fieldwork at and around Angkor Borei have done much to shed light on the processes of early state formation in the region. Dr. Stark developed a preliminary typology of earthenware ceramics for the Mekong Delta, as well as elucidating settlement patterns, emerging urbanism, and sociopolitical complexity in Early Historic Southeast Asia. From 2010 to 2015, Stark extended her Cambodian research to include the Angkorian period as a co-investigator with the Greater Angkor Project (GAP) and led field projects at multiple sites throughout the Greater Angkor region. Her political economy research focused on residential patterning within state temple enclosures. Since 2018, Stark has co-directed the Pteah Cambodia Project, whose current research, in collaboration with Cambodia's Ministry of Culture and Fine Arts, is on examining

Angkorian and Pre-Angkorian habitation areas and temple communities outside Greater Angkor, in Battambang Province, Cambodia. Dr. Stark has received funding from the Australian Research Council, the Center for Khmer Studies, Earthwatch Institute, the Henry Luce Foundation, the NASA Space Archaeology Program, National Endowment for the Humanities, National Geographic, National Science Foundation, and Wenner-Gren Foundation, among others.

Dr. Stark is a major promotor of Asian and Southeast Asian archaeology as a field. She served as Editor-in-Chief of the journal *Asian Perspectives* from 2002 to 2006 and edited the *Archaeology of Asia* (Stark 2006). Recent scholarly work has focused on synthesizing long-term historical trends in Cambodia and Southeast Asia more broadly. These syntheses have been published in venues accessible to a wide range of scholars, which has served to promote and emphasize the relevance of this work to those outside the region and outside archaeology. Additionally, Stark actively participates in interdisciplinary workshops and conferences, connecting diverse perspectives. This includes co-organizing a conference session at the Association of Asian Studies meeting that brought together archaeologists and historians of Southeast Asia and as a speaker at recent conferences on historical ecology and indigenous knowledge and science.

Dr. Stark is actively involved in cultural heritage preservation in Southeast Asia. In 2003 she contributed to the development of a bilateral memorandum of understanding between Cambodia and the United States to impose import restrictions on Cambodian archaeological materials and was involved in the renewal of this agreement in 2008, 2013, and 2018. She developed museum exhibits for the Angkor Borei site museum in 1999 and worked to upgrade the exhibits and organize funding for museum renovations from the US Embassy in Cambodia that were completed in 2019. In 2017, she facilitated the repatriation of archaeological materials from fieldwork in the 1960s held at the University of Hawai'i to the Ban Chiang Museum, Thailand.

Dr. Stark is actively working to decolonize Southeast Asian archaeology through opportunities for indigenous scholars. From 2007 to 2012, she directed the Luce Asian Archaeology Program (LAAP) funded by the Henry Luce Foundation, which provided English language and archaeological training and professional development skills to junior scholars from East and Southeast Asia. She regularly takes part in training programs and workshops to promote Southeast Asian scholarship on topics such as ceramics analysis, the use of GIS in archaeology, and Cultural Resource Management. Dr. Stark has worked tirelessly to foster indigenous scholars through these programs, as well as through the intangible support of mentorship, editing drafts of manuscripts and grant proposals, and building intra-regional connections of scholars across Southeast Asia. Many of these scholars have gone on to pursue advanced degrees, published their work in peer-reviewed journals, and received competitive funding awards for their own research projects.

In addition to her scholarship, Stark is committed to teaching and outreach. She has served on the committees for over 75 B.A. Honors degrees, Master's theses, and Ph.D. students. In 2016 she was the recipient of the University of Hawai'i Chancellor's Citation for Meritorious Teaching. She regularly speaks about archaeology to the general public, including lectures through the Archaeological Institute of America and the Girl Scouts of Hawai'i.

Starosele Middle Paleolithic Site with Hominin Remains

Yuri E. Demidenko
Crimean Branch, Institute of Archaeology, National Ukrainian Academy of Sciences, Simferopol, Crimea, Ukraine

Introduction

The site of Starosele was discovered in the 1950s with Middle Paleolithic artifacts apparently associated with human child remains, possibly transitional to *Homo sapiens* or modern *Homo sapiens*. The discovery was seen as a kind of Eastern European sensation or mystery, mainly due to the Levantine Skhul/Qafzeh hominin discoveries also in Mousterian archaeological context, found in the 1930s. New excavations in the 1990s at Starosele have helped to clarify many archaeological, anthropological, and chronological aspects of the site's finds.

The site is located within the Kanly-Dere, a side, currently dry box canyon in Eocene limestones running north into the Bakhchisaraiskaya valley at the village of Starosele, now within the northern edge of the town of Bakhchisarai in southwestern Crimea. The site is not a cave as was suggested during its excavations in the 1950s but, as became certain during the 1990s excavations, rather an accumulation of sediments on a rock platform along the base of the eastern side of the canyon, 11–13 m above the canyon bottom.

Key Issues/Current Debates/Future Directions/Examples

Starosele: Discovery and the 1950s Excavations

The Middle Paleolithic flint artifacts were found in 1952 on a rock platform in Kanly-Dere canyon by N.P. Katsur, an associate of the Bakhchisarai Museum. A young archaeologist from Moscow, A.A. Formozov, then conducted excavations there from 1952 to 1956. The excavation data were described in a series of articles and a book (Formozov 1958) and can be summarized as follows (see also Demidenko 1998).

Formozov excavated a total area of c. 250 sq. m (Fig. 1). Only during the last two field seasons, in 1955 and 1956, when c. 140 sq. m. were excavated in the main site area, were both a 1-m^2 grid system and several datum points established. Vertical subdivision of the deposits (with an overall thickness of 2–4 m) albeit with no separation of different lithological horizons was also done in 1955–1956 when artifacts and fauna were collected separately from deposits above and below a level of thick limestone slabs. In addition to abundant flint artifacts (c. 12,000 pieces) and fauna (c. 60,000 items), a human child burial was discovered in 1953; separate bones of an adult woman were identified only after the 1954 excavations during analysis of the fauna. The burial came to be known as the famous "Starosele child," while the other remains with fully *Homo sapiens* morphology were generally ignored.

Formozov himself came to the following conclusions after the first Starosele excavations: despite considerable vertical stratigraphic artifact distribution, the site represented a continuous human occupation during the Last Interglacial, in the 1950s in Soviet archaeology considered to be Late Mousterian; the flint industry was homogeneous throughout the site and was Mousterian "with a bifacial tool tradition"; the Starosele humans were engaged in specialized hunting of

Starosele Middle Paleolithic Site with Hominin Remains, Fig. 1 Starosele site. Plan of the excavations at the site: the 1950s excavations, and the 1990s with heavier line. *Stars* indicate human burials: J-20 – 1953 Starosele child; C-29/30–1954 adult female remains found in fauna materials; I-22 – 1993 infant; H-25 – 1994 adult. (Modified after Marks et al. 1996: Fig. 2)

Equus hydruntinus; the "Starosele child" was contemporaneous with the site's Mousterian occupation; and the child was evolutionarily "transitional" between Neanderthals and modern *Homo sapiens*.

Starosele: Interpretations After the 1950s Excavations

The Starosele geochronology was considered to be mainly Last Glacial due to the presence of mammoth, woolly rhinoceros, reindeer, and arctic fox (Ivanova 1965; Klein 1965).

Archaeologically, V.N. Gladilin (1976, 1985) proposed the most interesting and valuable interpretations for the Starosele lithic assemblages. He considered the industry to be a separate Starosele type within the East European Micoquian. Although he discussed the site's flints as a single unit, he noted some differences for artifacts above and below the limestone slabs. Accordingly, he considered Starosele to contain two Mousterian layers and hoped for future lithic analyses by layers rather than a single assemblage.

Such analyses were done by V.P. Chabai in the late 1980s in Moscow for his doctorate (Chabai 1991). The presence of Levallois radial cores in "layer 2" (below the limestone slabs) and their absence in "layer 1" (above the limestone slabs) was the only significant difference observed between the two assemblages in the Moscow collections after the 1955–1956 excavations. At the same time, the abundance of both unifacial and bifacial convergent points in both assemblages allowed Chabai to exclude Starosele from the

Starosele Middle Paleolithic Site with Hominin Remains, Fig. 2 Starosele site. East/west profile along line 23/24, squares H and K (2 m to the south of Formozov's 1956 profile). *I–IV* – archaeological levels; *A–F* – geological units (After C.R. Ferring) *A* – modern soil; *B* – complex of alluvial and colluvial sediments; *C* – exfoliated limestone slabs with layer of fine sediments in between; *D* – gravels and exfoliated limestone fragments; *E* – boulders in red clayey matrix. (Modified after Marks et al. 1996: Fig. 4)

Eastern Micoquian, defining it instead as a separate Crimean Mousterian industry of Starosele type with bifacial tools.

The Starosele child was also viewed differently by different specialists. Doubts were raised about the strict association of the child with the Mousterian layers (e.g., S.N. Zamyatnin, M. Gabori, R. Klein) as well as interpretation of its anatomic features as being transitional to modern *Homo sapiens* rather than fully modern (e.g., G.F. Debets, A. Thoma, V.P. Alexeev). There was thus no common agreement on either the nature of the archaeological context or the anthropological features of the child. It is also worth noting that the Starosele child was never anthropologically defined as a Neanderthal.

As a result, new excavations at Starosele were needed to clarify its geological and cultural stratigraphy, geochronology, and nature of the lithic assemblages throughout the stratigraphic sequence and potentially shed light on the nature of the human remains.

Starosele: The 1990s Excavations

A joint Ukrainian-American research program directed by A.E. Marks was carried out in 1993–1995 (see also Marks et al. 1996, 1997; Marks and Chabai 1998; Marks and Monigal 1998; Chabai et al. 1999; Chabai 2004). An area of c. 40 m^2 was excavated near the southern edge of the 1956 excavation zone (Fig. 1). The c. 4-m-thick profile analyzed by R. Ferring showed the presence

Starosele Middle Paleolithic Site with Hominin Remains, Fig. 3 Starosele, level I – selected flint artifacts. *1–2* – cores; *3–4* – denticulates; *5–6* – notches; *7* – lateral end-scraper + ventral side-scraper; *8* – burin + perforator. (Modified after Marks and Monigal 1998)

of various deposits of different origin (Fig. 2). Four stratigraphically distinct archaeological levels were identified within the sequence. Three of these levels – IV, II, and I (from bottom to top) – are comparable to the 1950s Middle Paleolithic flint industry, containing mainly points among bifacial tools, now attributed as the Starosele industry type of Crimean Micoquian Tradition (Fig. 3). But surprisingly, the level III assemblage lacks any such bifacial tools and at the time had no comparisons within the range of Crimean Middle Paleolithic industrial variability. It was only in the 2000s that the present author (Demidenko 2003–2004) demonstrated that the Starosele level III assemblage (Fig. 4) was quite similar to the assemblage from the lower layer at Kiik-Koba. A systematic dating program was also carried out, as well as analyses of the fauna, microfauna, and malacofauna recovered from the different archaeological levels. The proposed discontinuous geochronological sequence can be presented as follows: Early Last Glacial Interstadials (Amersfoort-Broerup & Odderade) for level IV, Lower Pleniglacial for level III, Moershoofd Interstadial for level II, and Hengelo Interstadial for level I.

Starosele Middle Paleolithic Site with Hominin Remains, Fig. 4 Starosele, level III – selected flint artifacts. *1* – bifacial perform; *2–4* – various unifacial side-scrapers on bifacial reduction debitage; *5–6* – bifacial leaf points. (Modified after Marks and Monigal 1998)

Finally, new remains of modern humans were discovered during the 1990s excavations. A destroyed infant burial was found in 1993 protruding from Formozov's 1956 line 21 profile. An additional burial of a middle-aged adult was exposed in 1994, some 2 m south of this infant burial (Fig. 5). The infant burial had no clearly visible pit, but the skeleton lay fully within modern sediments, the top of Middle Paleolithic level 1 being some 10 cm below it. The adult burial had a clear burial pit originating in modern sediment and cutting through the Middle Paleolithic level I sediments, ending on the top of the exposed exfoliated limestone slabs. The infant burial included only the legs and feet, while the rest of the remains were most likely destroyed by Formozov's team when they sealed the 1956 southern profile. The infant's legs and feet indicate that the infant was buried in a semi-flexed position on its right side, with its head oriented to the west. The adult burial, with a complete skeleton in extended anatomical position, was oriented east–west with the head to the west and the face to the south. There were no grave goods, but some Middle Paleolithic flint artifacts and fauna were mixed into the pit fill.

There are many similarities between the 1950s Starosele child and the 1990s modern human burials that make their association highly likely (Fig. 5). All three burials are located within a small area in a line of c. 5 m. Both the 1950s child and the 1990s adult burials were in the same stratigraphic positions – below the uppermost Middle Paleolithic level, resting on top of the exfoliated limestone slabs. There were no grave goods, but some Middle Paleolithic artifacts and animal bones were found above them in the sediments. In addition, both skeletons were in the same position, with the same orientation. Such similarities between the 1990s clearly recent

Starosele Middle Paleolithic Site with Hominin Remains, Fig. 5 Starosele. Drawings of the 1994 adult burial and the 1953 child to scale, showing comparable body orientations and positions. (Modified after Marks et al. 1996: Fig. 7)

adult burial and the 1950s child burial considered to be of Middle Paleolithic age and being only 3 m apart seriously question the Middle Paleolithic affinity of the 1950s child. Moreover, it is well known that Kanly-Dere canyon was a traditional burial area during late medieval times and a seventeenth–/eighteenth-century Muslim cemetery existed about 100 m from the Starosele site. The two complete 1950s and 1990s human burials at Starosele reflect traditional Muslim burial practices with an extended position on the back, head to the west and face to the south, toward Mecca. Thus, both direct and indirect data strongly support the argument that all of the Starosele human burials, including the 1950s child, are of quite recent, clearly post-Paleolithic age.

Short Summary

The 1990s excavations at Starosele have led to many clarification of site context. Sediment deposition took place during the Last Glacial period over a long period from c. 100,000 to c. 40,000 BP. Human visits of the site were both frequent and episodic, likely separated one from another by no less than 5–10,000 years. Industrially, the Middle Paleolithic assemblages are grouped into two very different industry types – Micoquian (levels I, II, and IV) and Kiik-Koba, lower layer (level III) ones. Finally, the famous 1950s Starosele child is now accepted to be an intrusive late medieval burial with Muslim burial practices, like the other modern human burials discovered at the site.

Statues and Monumental Art in Archaeology

Jo Anne Van Tilburg
Cotsen Institute of Archaeology at UCLA, Los Angeles, CA, USA

Introduction

This entry samples a limited range of monumental art from selected archaeological sites in discrete environments within both continental and island settings. All are unique, yet there are discernible threads of common or contrasting human experience and expression. Monumental architecture and sculptural objects, no matter where they occur, are most often the original products of shared social and aesthetic values or religious belief. The upright bluestones of Stonehenge, the repeated notes echoed by the aligned stone statues of Easter Island, and the buried ceramic legions of Xi'an, China, were all inspired by an intensity of human commitment within societies that differed radically in terms of population size, natural resources, food production, and social organization.

Definition

Monumental art is defined here within the context of megalithic structures. It occurs widely, at all levels of social complexity and in differing local environments; as such, a universality of monumental art is claimed. Nonetheless, discrete development sequences vary according to regional phases or patterns (Mohen 1989: 285). Megalithic sites in Western Europe postdate the oldest painted caves of France, most of which were built c. 5,000 to 3,000 years before the Christian era. Megalithic cultures existed in the British Isles, Northern and Central Europe, the Near East, and the Central Mediterranean. Earthworks and burial mounds reaching megalithic standards occur widely at pre-Columbian sites in the Western Hemisphere. Kalasasaya is

an architectural complex near Pucara, Peru, including early zoomorphic stelae and later anthropomorphic sculpture. El Infiernito near the town of Ráquira, Colombia, produced megalithic burial structures. The Fraile stela and other monumental art objects in the Tiwanaku region are world famous. Megalithic sites in such places as Madagascar date to the eighteenth century.

Simply stated, a megalith is a large block of standing or upright stone (from the Greek *mega*, large, and *lithos*, stone). A single, isolated upright stone is a monolith (from the Greek *mono*, one, and *lithos*, stone; Fig. 1). Some upright stones in southern Spain, Portugal, Ireland, Scotland, and certain areas of France, whether isolated or clustered in groups, are embellished by incised or bas-relief symbols (petroglyphs), most of which are curvilinear abstractions. Highly stylized representations of a corpulent female figure or the outlines of tools associated with male tasks or activities are also sometimes depicted. An iconographic continuity in such simplified two-dimensional art over a wide area is evident. Explanations for similarities in basic symbols are often hotly contested; one interpretation draws on neuroscience and attributes such similarities to the ancient spiritual practice of shamanism (Lewis-Williams and Dowson 1988, 1990).

Statues and Monumental Art in Archaeology, Fig. 1 Near Crear, Scotland, 2005, David Scheinbaum, 2012. (Courtesy of Scheinbaum & Russek Ltd., Santa Fe, NM)

Megalithic structures are most often a function of burial practices and associated with peoples who were sedentary and practiced agriculture. Population and food production models for Neolithic societies are estimated in relation to the size and extent of associated megalithic remains. It is suggested that populations ranging from 100 to 10,000 persons created megalithic grave sites while living within areas of 3–100 km, respectively (Mohen 1989: 205). The trend over time is from multiple burials to individual graves, suggesting an evolution toward greater social stratification.

Monumental art evolved out of megalithism (Fig. 2). "Monument" and "monumental" are variously defined. Monument is defined here as an object that is of or related to a sepulcher and may include free-standing, three-dimensional figures as well as architectural embellishment. Figures may be either anthropomorphic or zoomorphic, although distinguishing features of both may be combined, and variant stylistic categories are defined for discrete societies or areas of the world (Van Tilburg 1991). Monumental art is characterized as being of good-quality material, immense in bulk or size, durable, and invoking memory. The precise size range varies with individual study areas or regions, and in nearly all cases, relative scale is a far better indicator of monumentality than is total length or height.

The monumental art that is the most lasting and of greatest archaeological interest is most often wrought in stone but also fabricated of less durable clay, wood, fiber, and textiles. It is stone, however, that embodies, as material and medium, the virtues of density and durability that translate into symbolic values of power and longevity

Statues and Monumental Art in Archaeology, Fig. 2 Rano Raraku, Easter Island (Rapa Nui), 2003, David Scheinbaum, 2012. (Courtesy of Scheinbaum & Russek Ltd., Santa Fe, NM)

which, in turn, signal tradition and continuity (Van Tilburg 2006). These inherent qualities have made stone the material in which human culture groups of varying complexity have expressed a denial of time and rejection of death, asserted status, preserved memory, and professed belief.

Historical Background

Discerning the interaction of ancient architectural sites within discrete environments reveals an instructive range of practical, political, and aesthetic variables, as well as patterns of human choice and ecological stasis or change. Modern archaeologists are concerned with how natural resources were exploited by builders and pay close attention to how monumental art objects are situated relative to their respective ancient and contemporary landscape features. Most natural scientists today understand that climates are capable of radical change over long periods of time, and archaeologists, in turn, are concerned with how such changes impact the landscape within which megalithic art objects are situated or were once perceived.

For example, it has been shown in American deserts that basaltic and other hard and dense rocks, when their surface "skin" is broken, subsequently interact with the environment to, in effect, gradually "heal." This takes place over generations and is the result of the surface formation of a patina known as desert varnish. Petroglyphs, created by carvers who incised, scratched, or otherwise pecked away stone surfaces with stone tools, are often re-varnished. More recently made petroglyphs are perceptively different in color, hue, and texture than older ones. This suggests that the stone's changing surface characteristics may be indicators of iconographic progression.

Enduring monumental art objects and architecture in many ancient cultures were produced when observation of the natural world was experimentally combined with human talent, experience, or belief. Nature's extravagant displays of shape and form, for example, may suggest to the perceptive artisan inherent and underlying principles of order. The wind-driven sand dunes of California's Death Valley are natural sculpture in motion. Monument Valley in Utah and the Grand Canyon of Arizona, to even the most unromantic eye, appear to be sensitive and captivating natural sculptural installations. The deep, dark caves of Paleolithic France and Spain surely played a role in the aesthetic development and ritual behavior of those who created the paintings on their walls.

In many cultures, the organizing strategy of supernatural belief and social interaction that produced religion was fundamentally related to nature and to the transformative power of nature (Hunt et al. 2010). Many of the world's ancient religions appear to have revered nature. Even today, the Japanese religion Shintō teaches that rocks are endowed with special qualities deserving of respect. Rocks placed sensitively in the

landscape are basic elements of Zen gardens (Fig. 3), and complex symbolic meanings are associated with their size, shape, color, texture, and position. A standing stone symbolizes the heavenly realm; a horizontally placed rock symbolizes earth, and a rock placed diagonally represents the whole of humanity.

Creation, procreation, fertility, fecundity, and human sexuality are often referenced in stone carvings embellishing mortuary or temple buildings, with monolithic male and female figures staged independently or paired (Figs. 4 and 5). Male and female genitalia are depicted both graphically and symbolically in two-dimensional rock art and three-dimensional sculpture of many cultures. At other times, the genitalia on sculptural objects are conspicuous in their absence. Major landscape features in some Pacific Island cultures were conceptualized as parts of the human body, including especially male genitalia. Entire landscapes are sometimes seen as reclining or standing human figures, usually named for mythic heroes or gods. On the island of Tongareva in the Cook Islands, a sprawling, complicated, and sacred site (*marae*) called Te Papa-o-Sokoau was constructed of stone walls laid out in the form of a headless, sexless human body (Kaeppler et al. 1993; Kaeppler 2008: 151).

The ancient Olmec emphasized the human head in their megalithic stone sculptural objects (Coe and Diehl 1980). They sculpted massive, elaborate portrait sculpture of ruling male personages embellished with the bas-relief signs and symbols of social status and leadership. These

Statues and Monumental Art in Archaeology, Fig. 5 Kanchipuram, India, 2000, David Scheinbaum, 2012. (Courtesy of Scheinbaum & Russek Ltd., Santa Fe, NM)

heavy objects, moved over great distances, were carved of specially quarried, dense, and dark basalt.

Social organization and the means of food production are two fundamental variables associated with monumental art. Easter Island (Rapa Nui) was organized as an Eastern Polynesian-type chiefdom, with 10 or 12 individual patrilineal groups (usually described as "clans" or "tribes") descended from the sons of the founding ancestor. Over time, these lineages aligned as two large political entities characterized as confederations (Routledge 1919; Van Tilburg 1994). The ancient carvers created over 1000 monumental sculptures in human form under this system, with about half of them transported to lineage agricultural lands bordered by traditional fishing grounds. There they were erected on stone platforms (*ahu*) and presided over what is inferred to be mortuary rituals. Most researchers agree that the vertical stone statues of Rapa Nui evolved from stone backrests raised on other Polynesian sacred sites.

Micronesia, on the other side of the Pacific, includes the Republic of Belau (Palau), the Yap Islands, Kosrae, and the Mariana Islands, among others. The matrilineal society of Belau raised large stone monoliths, some of which are carved with combined anthropomorphic and zoomorphic features. At Melekeok on the island of Babeldaob, a group of nine ancient and grotesque stone monoliths is known as the "Great Faces" (Van Tilburg 1991). Massive terraced earthworks on the same island were sculpted from natural hill formations.

In the Mariana Islands c. 1000 CE, elaborate wood structures known as *latte* houses were raised on monolithic stone columns and capstones that are, in fact, an abstraction of the upright human form. The largest of these structures, most of which served as community meeting houses, is found on the island of Tinian, northeast of Guam. There, one of 18 aligned *latte* is known as the House of Taga.

The megalithic, elite ceremonial center of Nan Madol is on the island of Pohnpei. The mortuary enclosure of Nandauwas is at the heart of the complex and its greatest megalithic achievement. Built sometime around 1200–1300 CE, Nan Madol is a sprawling marvel constructed of stacked prismatic basalt upon artificially created islets, canals, and inlets (Morgan 1988: 58–85).

In island Southeast Asia megalithic stone and wood statues, stone seats, and ornately embellished sacrificial posts are all known.

The Lapita culture emerged at least 2,000 years before the Christian era, and its proximate center is in the Bismarck Archipelago. Lapita people spoke Austronesian languages, developed maritime traditions, and became the founding culture of parts of Melanesia and Polynesia. On the Southeast Asian island of Nias, off the Sumatra coast, vertical stones, isolated or in groups, were called *behu* (Feldman 1988: 39, 49) and often carved as human figures and associated with chiefly houses and burials.

The ancient Aztec, in contrast to the less stratified societies of the Pacific island groups, created a vast and nearly unmanageable continental empire ruled by fearsome deities conceptualized in dual, quadruple, or quintuple forms (Pohl and Lyons 2010). Ornately carved and painted sculptural objects in clay and stone, as well as complex architectural figures, adorned monuments commissioned by rulers who demanded and extracted extravagant tribute from conquered peoples. Human sacrifice was considered a sacred duty and debt to the gods, and festivals were dedicated to warfare and the promotion of agricultural fertility. Religious ideology was inextricably linked to political supremacy, and monumental art supported rituals of idealistic communication and social domination.

Whether the project is a monumental, communal building task of epic social meaning, or a single statue carved at the behest of a powerful benefactor or commissioning chief, stone carving is a challenging task and valued skill in all cultures. Mastery of tools and technique is required but so, too, is a sensitive discernment of cultural values. Ancient craftspeople were required by the norms of their societies to capture and realize key emotional and spiritual content shared by their entire cultures. Most ancient stone sculpting traditions probably grew out of woodcarving, and large wood pole sculptures are the precursors to stone figures in many megalithic cultures. Quarrying, carving, and sculpting any stone require the reduction of resistant material rather than the building up of form that is the goal when other more pliable mediums such as clay or plaster are used. Stone carving was a profession of high status and power. Carvers formed guilds and secret societies with their own proprietary gods, goddesses, and priests. Members had their own emblems and insignia.

The aesthetic success of a three-dimensional carving requires the participation of the viewer as well as the creator. People brought up in Western cultures generally think they perceive three-dimensional form, but few realize that full perception is also the result of being trained to comprehend the empty spaces of landscape or architecture that give shape to objects. Contemplation of an ancient sculpture as an art object in a museum gallery, where it is far removed from its original context, cannot reveal the object's original charismatic or iconographic role and often leads to stereotypical conclusions of dubious value to understanding the past.

Sculpture that is truly three-dimensional should vary when it is looked at from different angles. Sculptures of the human form that are nearly symmetrical provide only half of the potential opportunity the viewer needs to perceive the relationship between space and form and setting and object. Fully symmetrical human forms, however, are also unnatural, as anyone can see by studying their own face in a mirror. Symmetry analysis in anthropological perspective has relevance in our attempt to understand the patterns of communications established and facilitated by megalithic and other art forms (Washburn and Crowe 1988).

Sculptures that are presented as architectural relief are most successful when at least some of their elements project outward from the wall (Fig. 6). On some sites the architects and sculptors of the past seem to have used the interplay of sun and shadow on walls carved in relief to create substantial visual drama. That achievement was probably an aspect of stating or creating power through the implied status of the building owners or through ideology.

The natural surface irregularities of unpolished stone are often incorporated into or enhanced as features of two-dimensional rock carvings. Nonrepresentational or supernatural figures of many types are common in the rock art and relief sculpture of many cultures. Uneven, coarse surfaces, natural stone texture, color discontinuation, and other stone surface anomalies often become valuable aesthetic or symbolic assets in carvings that blend opposite imagery (e.g., male/female or human/animal characteristics).

When prehistoric architecture passes into ruin yet continues to remain in the natural landscape of sun and shadow, it inevitably becomes aesthetically the same as a three-dimensional sculpture. Well-constructed stone walls are almost always sculptural, whether they are propped and chinked with skill and an eye to aesthetics or

Statues and Monumental Art in Archaeology, Fig. 6 Bayon, Cambodia, 2009, David Scheinbaum, 2012. (Courtesy of Scheinbaum & Russek Ltd., Santa Fe, NM)

running in linear patterns across a challenging landscape. The ruins of Hadrian's Wall in northeastern England and the more intact Great Wall of China both elicit in modern viewers similar feelings of technological and aesthetic awe.

Key Issues/Current Debates

The study of megalithic cultures is concerned with reconstructing methods of sociopolitical complexity and mechanical engineering, the creation and implementation of ideological structures, iconographic analysis, the natural settings of sites, human and natural resources, and spatial and landscape analysis. Research questions are often posed within such theoretical constructs as experimental archaeology, cognitive archaeology, landscape and ecological archaeology, and iconography. Within each of these subfields are key issues and current debates.

A certain universality of symbol types common in two-dimensional rock art has been discerned in similar natural environments. The neuropsychology of iconography, as noted above, deals with these similarities and their longevity in human culture in the context of the religious beliefs of shamanism. However, also as noted, this interpretation has been aggressively challenged.

The engineering expertise of megalithic societies is often examined within the research structure known as experimental archaeology. Sculptural replicas have been devised and manipulated to suggest ancient transport methods. In nearly all cases, common sense has prevailed or provided adequate guidance for these experiments, and variables are usually limited to wood, rope, and countless hours of motivated human effort. Such research is most insightful when it seeks to elucidate patterns of social organization, religious belief, resource territory size, and food production methods within well-structured population models (Van Tilburg 1993; Van Tilburg and Arévalo Pakarati 2002; www.pbs.org/wgbh/nova/easter).

All archaeological sites, including megalithic sites especially, must be considered within the physical conditions that prevailed when the site was active (Vita-Finzi 1978). Modern archaeologists often survey large areas and conduct systematic studies of monumental object distribution and spatial patterning (Hodder and

Orton 1976). Debate in recent years has dealt not only with the occurrence of monumental art but also its relationship to natural resource depletion or environmental destruction and social structure collapse. Key issues of global conservation in our modern world have been projected upon the peoples and cultures of the past. The trajectory of stylistic and other changes in monumental art is often related to political complexity but must be anchored by carefully constructed time frames.

International Perspectives

The stone architecture of Cambodia and the toppled statues of Rapa Nui are instantly recognizable as iconic symbols and graphic reminders that however durable stone is as a material, all prehistoric and other ancient stone buildings and sculpture will diminish with time (Fig. 7). Without strenuous and enlightened global preservation efforts, the forces of weather and time will inexorably wear away the surface of megalithic objects, and the sculptural material itself will ultimately be returned to the natural matrix from which it came. Loss of any part of our shared human heritage is indefensible because science and art pose as yet unanswered questions.

Future Directions

Monumental art often encourages cross-cultural comparisons. This is due to broad pattern similarities such as placement relative to mortuary sites. Yet each culture interacted with the immediate natural environment in its own unique way. Each flourished because food production strategies resulted in surpluses allowing redistribution systems that underpinned building projects. Failure to sustain productivity and to integrate it with social growth is a recurring theme, and the theory of social and political systems collapse is based, in part, on the inferred mismanagement

Statues and Monumental Art in Archaeology, Fig. 7 Ta Prohm, Cambodia, 2009, David Scheinbaum, 2012. (Courtesy of Scheinbaum & Russek Ltd., Santa Fe, NM)

of human and natural resources. The cultures that produced monumental art include chiefly societies and states. Understanding the motivations of humans living with differing social structures and who created monumental art may provide insight into a more sustainable future for us all.

Stature Estimation

P. Willey
Anthropology Department, California State University, Chico, Chico, CA, USA

Introduction

Estimating stature from human remains is important for understanding the human osteoarchaeology of past populations as well as providing information for forensic comparisons with recent missing persons.

Stature consists of a living person's standing height. It is measured from the top of the head (vertex) to the ground surface while the person stands in an upright posture, heels placed together, and head positioned in the Frankfort Horizontal.

In the first subdiscipline, human osteoarchaeologists analyze and interpret samples of human remains, skeletons from archaeological sites. They use stature estimations as an indication of overall size, searching heights for trends,

documenting evolutionary and secular changes, and revealing geographic variation, sexual dimorphism, and health. With those data in hand, osteoarchaeologists employ the relationship between stress and stature to contrast better adapted with more poorly adapted populations, and more affluent times with more stressful periods.

In the secondary subdiscipline, contemporary forensic anthropological applications use stature estimations to assist identification of deceased unknown individuals. Forensic anthropologists estimate stature as part of a biological profile, other biological parameters including sex, age, and ancestry. Combined with other biological characteristics, estimated stature of recovered remains supports inclusion or exclusion of a missing person as a potential match for the unidentified remains.

Adult stature results from the influences of genetics, environment and their interactions that affect linear growth and culminate in height attained during early adulthood. Genetic influences have a considerable impact on stature (see Visscher 2008; Weedon et al. 2008).

In addition to genetic affects, environmental perturbations influence growth and ultimately attained adult stature. Those distresses may stimulate the developmental plasticity associated with stressful and beneficial periods. Stresses may interrupt, retard, and delay growth. If compensatory catchup growth is sufficient to compensate for these delays, growth deviations show little permanent mark, affecting growth only temporarily. On the other hand, long-term, persistent, and major growth insults may have a pronounced sway. When rebound growth is insufficient for complete compensation, the growth insults result in reduced attained adult height. Generally poorer environmental conditions during growth cause slowed, incomplete growth and result in shorter persons.

These principles are employed by many disciplines for various ends. They include economists (e.g., Komlos 1994), medical specialists (e.g., de Onis and Habicht 1996), human rights proponents (e.g., Kent 2009; Toebes 2009), and social political advocates (e.g., Boix and Rosenbluth 2014). Human osteoarchaeologists and forensic anthropologists ally themselves with these other disciplines when including stature estimation in their studies and practices.

State of Knowledge

Although the goals of osteoarchaeologists and forensic anthropologists differ, both fields use two methods to estimate stature. The two fundamental approaches consist of measurements of a whole skeleton or measurements of separate limb bones.

Whole Skeleton Approach

The first approach is the whole skeleton or "anatomical" method (e.g., Fully and Pineau 1960; Raxter et al. 2006). The method requires a complete – or at least a relatively complete – skeleton. All bone lengths and element heights contributing to stature are measured (Fig.1). Required measurements include skull height (basion-bregma), all vertebral body heights, first sacral segment, femur, tibia, and joined calcaneus-talus lengths. The atlas and axis require special attention. The axis (Cervical 2) body and dens epistrophis height are included in the sum, the latter serving as an approximation for the nonexistent atlas (Cervical 1) "body" height. After summing these skeletal measurements, the soft tissue component contributing to living stature is then added to the total. Additional soft tissue is estimated based on the sum of skeletal elements as a set figure based on the summation's interval (Fully and Pineau 1960) or estimated with a regression formula (Raxter et al. 2006).

Advantages of the whole skeleton approach include its accuracy of stature estimation regardless of sex, ancestry, time period, and anomalous numbers of vertebrae (e.g., Raxter and Ruff 2010). On the other hand, disadvantages of the approach involve it requiring a complete or almost complete skeleton, and the patience and time needed to measure and sum all element measurements contributing to height. Considering that missing elements often occur, an innovative step involves using regression to estimate missing

Stature Estimation, Fig. 1 Measurements needed to estimate stature using the whole skeleton approach. (Illustration by Judy Stolen, reproduced from Willey (2009)).

elements' lengths (Auerbach 2011), thus circumventing the first disadvantage.

Regression Approach

The second stature estimation approach is the linear regression or "mathematical" method. One of Karl Pearson's earliest applications of regression statistics involved estimating stature of archaeological remains, an approach that continues in widespread use today. The regression approach is mathematically straightforward and usually involves a complete limb bone's length

or multiple limb bones' lengths (e.g., Trotter 1970).

The analyst measures the limb bone length; chooses the most appropriate regression formula based on the individual's sex, ancestry, and time period; inserts the measurement into the formula; and computes the estimated stature. The standard formula consists of the following.

Estimated stature = a + bx ± SE.

Where **a** represents the line's Y-axis intercept (when x is zero),
b represents the line's slope (amount of increase or decrease in Y with one unit change in x),
x represents the limb bone length or sum of bone lengths, and
SE represents the standard error.

The regression approach provides accurate stature estimations when sex, ancestry, and time period are known, and when an appropriate standard for those parameters/groups exists.

Stature estimations employing this approach are most accurate for the middle of the founding sample's distribution, those individuals approaching the middle height of the base sample. It is also most accurate for those individuals with "normal" body proportions. Stature estimations for shorter and taller individuals and those people displaying unusual body proportions prove less accurate.

The regression formula with the smallest standard error is the most accurate estimation of an individual's stature. It should be employed above all others. Formulae involving the lower limb bone lengths usually have the smallest standard errors.

The regression approach has advantages over the whole skeleton approach if the skeleton is incomplete, and when time for measurements and summation is limited. On the other hand, its disadvantages relate to identifying the skeleton's correct sex, ancestry, and time period, and having an appropriate standard available for those parameters.

In the absence of complete limb bones, alternate approaches to these standards have been developed. Some regression formulae employ fragmentary limb bone dimensions (e.g., Steele 1970). Other formulae use short, nonlimb bone elements dimensions (e.g., Holland 1995; Klein et al. 2015; Torimitsu et al. 2015; Wilbur 1998).

In addition to regression, alternative statistical approaches have been recommended. The simplest stature estimation method employs a ratio. The stature-femur length ratio has been established (i.e., Feldesman and Fountain 1996). The femur length is multiplied by that ratio to estimate stature. Some researchers promote the ratio approach as superior to regression formulae (Feldesman and Fountain 1996). However, other authorities question this approach. The femur/stature ratio overestimates statures, especially those of tall individuals. It has a greater prediction interval, and therefore, is less precise than estimations associated with regression estimations (Meadows and Jantz 1995).

At a more sophisticated statistical level, Sjøvold (1990) proposes a weighted line of organic correlation. It minimizes the influences of sex, ancestry, and presumably secular trend. So when appropriate formulae do not exist or those biological parameters cannot be established reliably, Sjøvold claims his approach proves more accurate.

Konigsberg et al. (1998) recommend inverse calibration. Inverse calibration is more accurate when stature estimation of an individual employs a base sample with similar parameters as the individual whose stature is being estimated. If no comparable parameters can be established or an appropriate formula exists, then they recommend using the standard classical calibration.

Sometimes both whole skeleton and regression approaches are combined to estimate stature. Skeletal or body components are measured and those measurements used in regression formulae to estimate living stature. Most often, this combination of approaches has been employed using the spine to estimate stature (e.g., Jason and Taylor 1995; Terezawa et al. 1990; Zhang et al. 2015).

Key Issues and Future Directions

Archaeological and forensic anthropological applications of stature estimation hold some

limitations/challenges in common. Because goals of the two endeavors differ, however, other issues diverge between the two approaches. Those specific challenges will be considered latter.

Issues Common to Both Forensic Anthropology and Human Osteoarchaeology

A person's living stature varies by time of day (e.g., taller following a night's rest, Tyrrell et al. 1985, Krishan and Vij 2007) and the method of measuring (e.g., taller with neck stretched). Presumably stature measurements also show effects of inter- and intra-observer errors. These challenges, however, pale beside other impacts on stature estimations.

Few stature estimation techniques employ base samples with known, measured statures of living people and those same individuals' bone lengths following death. This dearth may prove profound. Many stature estimation standards rely on adjusting corpse length to approximate living stature. Depending on the congruencies between corpse length and stature during life, this analytical step may adversely alter the accuracy of stature estimations based on these standards.

Another challenge to accurate stature estimation involves the height decrease that older adults experience. As individuals pass through adulthood, their statures diminish from their young adult maximums. Such "shrinkage" is attributed to osseous tissue compression, particularly vertebral body decrease, and loss of soft tissue, especially intervertebral disc compression. If an accurate stature estimation of the person's height at the time of death is required, then age-related decreases must be considered.

The debates related to adult stature decrease include when this onset of decrease begins, and once begun, the rate that it occurs. Both onset and rate are variously reported by different researchers (Fig.2). The claimed age when stature decrease commences differs from 30 to 45 years. After commencement of stature decrease, the claimed rate of decrease varies from a steady 0.6 to 1.6 mm/year, while other studies find the decrease accelerates in an exponential manner. Consensus occurs on one issue, however; researchers find

Stature Estimation, Fig. 2 Different claims of age-related decrease in adult stature according to selected authorities. Note differences in commencement and rate of stature decrease. Trotter US cadaver sample (Trotter 1970). Miall et al. Welsh samples (Miall et al. 1968). (Illustration by Judy Stolen)

that older females lose more height annually than their comparably old male counterparts.

For accurate stature estimation of middle-aged and older individuals, the onset and rate of stature decline must be established. Onset and decline of stature probably differ depending on variation associated with the individual, sex, ancestry, and socioeconomic status. Those parameters need to be assessed and documented.

Issues Specific to Forensic Anthropology

Of the several major goals of forensic anthropology, the foremost is to aid identification of unknown human remains. That identification is supported, in part, by similarities between a missing person's antemortem stature and postmortem stature estimation of a skeleton. Challenges to making accurate comparisons of stature between the living and dead include reliability of antemortem stature records, absence of standards for under-studied groups, potential for estimating stature from tissue-covered remains, estimating subadult statures, and the scientific reliability of conclusions.

Antemortem records usually consist of self-reported heights, including dimensions recorded on a person's driver's license (e.g., Willey and Falsetti 1991). Those person's self-reported records often misrepresent actual stature, usually exaggerating an individual's measured stature. An approach to deal with these potential discrepancies between self-reported documents and actual measurements is "Forensic stature" (Ousley 1995; Wilson et al. 2010). Forensic stature estimates the height recorded on self-reported documents rather than actual measured stature.

On the other extreme from the often inaccurate, suspect self-reported statures are measured heights in antemortem criminal, medical, and military personnel records. They may prove more accurate sources of living stature than self-reported heights.

Recent unrest in many lands poses an additional challenge. Forensic emphasis on previously understudied groups requires specialized stature estimation standards to estimate their heights. As international attention turns to areas of recent strife, many groups from Latin America, southeastern Europe, southwest and central Asia, and Africa will require attention.

Estimating stature from soft-tissue-covered bodies and body segments continues to be a research area ripe for investigation. In mass fatalities, soft tissues often cover the skeleton. Lacking time, equipment, or authorization for maceration, stature may not be estimated. Recent studies use body segment dimensions to estimate height (e.g., Adams and Herrmann 2009). Such approaches employ vertebral column segments, fleshed limb lengths, and smaller body segments (e.g., feet, Pablos et al. 2013). Existing anthropometric surveys for many living groups provide the raw data needed for stature estimations based on body segments.

Subadult stature estimation methods need attention too. Infants, children, and adolescents die in forensic situations. As adults, subadults require identification too. Their identification may be aided by accurate, up-to-date living stature measurements made by family members and health practitioners. The whole-skeleton technique may be applicable to estimating stature of subadult remains, but only when the skeleton is complete, includes all epiphyses, and if an accurate soft tissue figure can be established. In most cases, however, practical problems confound this approach, especially from loss of smaller, fragile elements. Employing limb bone diaphyseal lengths in mathematical formulae to estimate stature may prove a more fruitful approach (e.g., Brits and Bidmos 2017; Ruff 2007).

At least as applied in the USA, the reliability of the forensic sciences has been questioned (National Academy of Sciences [NAS] 2009). Among the NAS's recommendations were establishment of best practices, formation of techniques' reliability and limitations, standardization of terms, and documentation of bias and human error. Established a year before the NAS's scathing critique, the Scientific Working Group in Anthropology (SWGANTH) anticipated many of the NAS's criticisms. SWGANTH's documents, including one on stature estimation, addressed many of those issues. With SWGANTH's dissolution in 2013, the National Institute of Standards and Technology, Forensic Standards Board, Organization of

Scientific Area Committees (OSAC), Anthropology Subcommittee took over those responsibilities and is in the process of establishing standards for the discipline, including stature estimation. Until OSAC's recommendations are published, the SWG documents remain in effect. Note, however, that SWGANTH's website has been removed from the web and its documents are no longer readily available.

Issues Specific to Human Osteoarchaeology

In addition to problems common to both subdisciplines and those specific to forensic anthropology, some issues remain particular to human osteoarchaeology. Those challenges include applying regression approaches to prehistoric skeletal series and the use of whole skeleton approach.

Archaeological skeletal samples often differ by time period and ancestry from the regression standards employed to estimate stature. Therefore, archaeological applications using the regression approach usually pose additional challenges beyond those difficulties associated with forensic cases. The whole skeleton approach, on the other hand, should be more accurate than the regression for most archaeological series. It should prove accurate regardless of body proportions that may change from one time period to another (representing secular change) and differing ancestries. Unfortunately, complete skeletons are rare in archaeological series. As a consequence, additional methodological modifications are required for accurate stature estimation.

Some practitioners combine the advantages of both approaches (e.g., Ruff et al. 2012; Pomeroy and Stock 2012). They apply the anatomical method to those few complete archaeological skeletons available to estimate stature using the whole skeleton approach. Then, they calculate regression formulae from whole skeleton statures and limb bone lengths. The derived regression formulae are applied to other, less complete skeletons from the same time period, ancestral group, and geographic region where those standards are established.

Alternately, other applications have used prone skeleton length. That length is measured in the grave to approximate stature. One study, however, shows that prone skeletal lengths measure less than the whole skeleton approach, thus apparently underrepresenting actual statures and presumably those formulae providing less accurate estimations (Petersen 2011).

Because applicability of sex, age, and temporally related body portions from modern standards to prehistoric specimens is poorly known, unique approaches have been suggested to overcome these deficiencies. Avoiding the uncertainty and incompleteness of most archaeological skeletons, limb bone lengths (usually femur or tibia) may serve as a proxy for size and overall height. The bone lengths are presented alone, without estimating stature. The problem with this approach includes possible allometric changes in trunk-limb and/or interlimb bone ratios through time. Such allometric changes may mask sexual dimorphism changes and secular trends.

Summary

Stature estimation of remains contributes to human osteoarchaeology and forensic identification of recent unknown individuals. The two most common approaches to stature estimation consist of using the whole skeleton and regression formulae involving limb bones. Both approaches provide relatively accurate estimations, although secular trends and the effects of age, sex, and ancestry must be considered, particularly when applying regression formulae. For less complete remains, less accurate techniques may prove useful. Those techniques rely on fragmentary limb bones and nonlimb bone elements. The future holds great promise for continued improvements of traditional approaches to stature estimation and wonderful potential for new ones.

Steffy, J. Richard

George F. Bass
Texas A&M University, College Station, TX, USA

Basic Biographical Information

J. Richard Steffy was born on May 1, 1924, in Lancaster, Pennsylvania, and grew up in the nearby town of Denver. From 1942, Dick, as he was known, served in the US Navy, mostly on a destroyer escort in the North Atlantic; he was discharged in December 1945 with the rank of electrician's mate, first class. After earning an associate's degree from the Milwaukee School of Engineering, he joined his brother in his father's local business, which initially did residential electrical work but expanded under Dick to design, install, and maintain electrical systems for factories. He married Lucille Koch in 1951.

From childhood Dick had enormous curiosity about ships. Uninterested in making models for display, his passion was to learn how ships worked, building and destroying research models in order to understand them. Thus, when he read a 1963 *National Geographic* article about a seventh-century Byzantine shipwreck excavated off Turkey, he wrote to George Bass, author of the article, and asked if he might built a research model of the vessel on the basis of its scanty seabed remains. Bass introduced him to Frederick van Doorninck, who was reconstructing the ship's hull on paper for his doctoral dissertation, thereby establishing a collaboration of more than four decades between the three. Steffy was soon lecturing annually to a graduate course on ancient seafaring established by Bass at the University of Pennsylvania.

A visit to Cyprus in 1971, at the invitation of Michael Katzev to study the hull of a fourth-century B.C. Greek ship Katzev had excavated

off Kyrenia, led Steffy to abandon his secure job, at age 47 with a wife and two young sons, to make a career as an "ancient ship reconstructor." Partly supported by a UNESCO grant, he spent the next 2 years reassembling the Kyrenia ship's hull from 10,000 fragments of polyethylene-glycol-treated wood, the first such restoration of a Mediterranean shipwreck.

Major Accomplishments

In 1973 he joined the Institute of Nautical Archaeology (INA) Bass and Katzev had created. When INA affiliated with Texas A&M University in 1976, Steffy, Bass, and van Doorninck established a graduate program in nautical archaeology. In addition to teaching a generation of "ship reconstructors," Steffy was soon the "ship expert" on the excavation of the American Revolutionary War *Defence* in Maine, and a colonial vessel raised from South Carolina's Black River. Research as a visiting professor at the University of Haifa in 1981 led to his book, with Lionel Casson, on the Athlit ram. In 1986 he returned to Israel to interpret a first-century BCE boat salvaged from the Sea of Galilee by Shelley Wachsmann. Later he was a consultant for the construction in Greece of a full-scale sailing replica of the Kyrenia ship.

In 1985 Steffy received a prestigious McArthur Award. His 1994 *Wooden Ship Building and the Interpretation of Shipwrecks* is considered the bible of the field he established. Later he coauthored the first volume on the eleventh-century Serçe Limanı wreck. An acclaimed public speaker, he retired from teaching in 1990. He died on November 29, 2007.

Stein, Marc Aurel

Susan Whitfield
The British Library, London, UK

Basic Biographical Information

Born in Budapest, Stein's family life and early education at the Lutheran school in Dresden nurtured his linguistic skills, useful for Central Asia with its polyglot Silk Road past. These were further developed by his university education in Vienna, where he studied Sanskrit and comparative philology, and Tubingen, for a Ph.D. on Old Persian and Indology. After receiving his Ph.D. in 1883, he studied Punjabi in London. He returned to Hungary for military service, equipping him with surveying skills that were to prove essential for desert explorations. Following his return to London in 1887, he secured a post in Lahore. He was to remain in British India for all of his life (Walker 1995; Mirsky 1998).

Major Accomplishments

Aurel Stein was the consummate desert archaeologist, but not of those "tame deserts" of Arabia, America, or South Africa "which might impress the town dweller . . . and in which whole tribes can wander about for long periods sure of finding water and grazing." He fell in love rather with the Taklamakan and Lop Deserts, where "the

absence of moisture bans not only human existence but practically all animal and plant life" (Stein 1933: 4–5). His love for these deserts' solitude and harshness was rivaled by that of his passion for interpreting the interaction between history and geography as revealed by archaeology. At their glacier-fed fringes, the Taklamakan and Lop both provided rich evidence of human existence conquering the extreme environments from the second millennium BCE through to the end of the first millennium CE. This was the arena in which Stein spent 30 years of his life exploring and excavating (Whitfield 2004).

He read voraciously from childhood, both of the travels of early travelers, such as Alexander the Great and the seventh-century Chinese monk, Xuanzang, who crossed the Taklamakan on his way to India, and of the excavations of contemporary archaeologists. Among the latter was Flinders Petrie (1853–1942), and Stein noted well the developing archaeological methodology including stratigraphy, seriation, and, most especially, attention to the smallest details. Stein quoted him in the introduction to his first major expedition, "To leave a site merely plundered, without any attempt to work out its history, to see the meaning of the remains found, or to publish what may serve future students of the place or the subject, is to throw away the opportunities" (Stein 1907: ix).

Stein wanted to be a pioneer and set his sights on an expedition to the southern oases of the Taklamakan desert in Western China: it "is not a part of the earth as easily accessible as Greece or Egypt or India" (Stein 1907: x). Among Europeans, only Sven Hedin preceded him to the region, but he had not carried out systematic archaeology.

Steins's First Central Asian Expedition (1900–1901) was meticulously planned and yielded rich finds and documentation about the first millennium Silk Road kingdoms of Khotan and Kroraina (Stein 1907). A second (1906–1908) and third (1913–1916) followed and were equally successful before political changes in China curtailed the fourth (1930–1931) (Stein 1921, 1928). On these he traveled further east into the Gobi and to the sites of Kharakhoto and Dunhuang, where he acquired his most famous manuscript finds (though not through archaeology) (Figs. 1, 2 and 3).

In the desert, the constantly shifting sands ensured there was little chance for stratigraphy. But Stein was meticulous in his record-keeping, taking notes, plans, surveys, and photographs. Of the Central Asian collections from this period – for Stein was soon followed by others – only Stein's all have a detailed provenance. This feat is the more remarkable, given the difficult conditions, and was achieved by prodigious energy and

commitment. His recurring malarial fever and constant dyspepsia did not stop him from working from before dawn to late into the night.

He planned his excavations for the autumn through to the spring: It was not possible to carry enough water for work in the searing summer heat. The winters were equally extreme but he used this to his advantage, taking blocks of ice for water supplies: The settlements he excavated also showed evidence of icehouses. Constantly shifting sands required large teams of local diggers. It is testament to Stein's foresight, preparation, and calm leadership that he managed these expeditions with no loss of human life and minimal loss of animals.

In order to reach the Taklamakan, Stein had to cross over the formidable passes of the Hindu Kush, Karakorum, and Pamir. He planned a different route on each of his expeditions and took advantage to carry out surveys of ancient ruins en route.

But none of these mountains were as challenging as the Kunlun, whose northern slopes provided almost no pasture. It was on a survey here that he had a rare moment when his caution was overruled by enthusiasm, leading to frostbite. He went on forced marches strapped to the back of a yak back across the mountains to Leh, where several toes were amputated (Stein 1921: 1326–7).

His finds in the Taklamakan uncovered unknown languages and cultures and put the eastern Silk Road kingdoms on the map of world history. But Stein did not stop archaeology after 1930. He led four tours of Iran and Iraq (Stein 1940), exploited new technologies in his aerial surveys of the limes of Jordan (Gregory and Kennedy 1985), and in his 81st year finally realized his lifelong dream of archaeology in Afghanistan. Unfortunately, he caught a chill and died within a week of arriving in Kabul: His grave is in the British Cemetery. His Iranian colleague on his fourth Iran tour noted: "Before finishing this report I must inform you of the following: one cannot call this tour a promenade. It should be called a journey of difficulty, of pain, of bitterness, of danger and illness." Stein, on the contrary, wrote that "compared with the Taklamakan and the Kun-lun travel both in these valleys and across the mountains seems very 'tame' work" (Whitfield 2004: 106).

Stewardship, Concept of

Alvaro Higueras
Simon Fraser University, Burnaby, BC, Canada

Introduction

Stewardship is today a concept that concerns the ownership, property, control, and promotion of a broad set of material and intangible goods, which include cultural heritage resources.

Definition

A Classic Definition

The role of steward, as in "steward of the castle" or "steward of the palace," is as ancient as the need to have supervision and organization of household or estate affairs. This administrative role probably occurs very early in prehistory as societies create hierarchical and complex administrations. Many references exist in historical documents to their economic and political role in Egypt of the Pharaohs both in the palace and the temples, in the urban settings of early Mesopotamia and its temples, and, more recently, in England in medieval monarchic times. The function of the steward is often exalted in Shakespeare plays: its importance in the management of the riches, gifts, tribute, and taxes making their way to the treasury of the sovereign or, often, in palatial intrigues.

A Current Definition

An intrinsic historical feature to the role of steward is that it manages property and wealth that belong to their masters and rulers. In this sense, the role of steward has changed entirely in the last two centuries. The tendency in contemporary times is that stewards own the heritage, goods, or valuables that they admire. A vital part of the current stewardship scenario is to have a close control over those goods. While the argument is

often that they hold the goods in custody for the public good, the fact is that those goods are held under a private property system and are obtained by the acquisition of goods in the free market or, more specifically, cultural heritage markets in auction houses or privately where objects are obtained from looting, commissions, theft, and legal exports (Kimmelman et al. 2006; Renfrew 2009).

Historical Background

The shift in the role of the steward, and therefore the concept of stewardship, is related to change in the economic structure of Western societies. The role of steward has continued to be a prestigious one, albeit its role has moved away from the governmental or the real estate spheres in which it originated (Cline 2003). The role of the "steward" in the period of rising capitalism of the nineteenth century, in contrast to its traditional role in a land-based economy controlling tenants, moved to spheres of urban settings with the predominance of new wealth based on industrial and trading economies with profits invested in cultural endeavors.

The founding of state museums open to the public in Europe in the nineteenth century, and art museums in the United States at the turn of the twentieth century, reveal the intentions of the new stewards: to show their private rooms with their private possessions and to display their antiquities and art in public spaces (and more rarely in their own homes). The crucial difference between Europe and the United States, along general lines of state versus private property, is that the latter reflects the will of their private holdings to be shown, not unlike the humanists of the fifteenth century in Europe and Italy in particular.

The new museums that opened in the United States in brand new buildings designed in neoclassical style had as their core attraction private collections displayed in custody and often bequeathed to them by the new "stewards" (e.g., the Mellon family as the core of the National Gallery in Washington D.C.). These museums would start building their own collections by various means: financing "research parties" to obtain the goods, buying collections or single artifacts at home and abroad, and continuing to promote to the collectors their image as a worthy depository for private collections to be displayed for the public good. The exact provenience of the objects is often not an issue: it is their artistic worthiness that is central.

UNESCO Über-Steward of World Heritage

The role of UNESCO in setting the bar for the protection of cultural heritage is crucial. UNESCO became the rightful global steward by setting rules at a time when rules of the game of heritage possession were sketchy, lax, and circumstantial. The UNESCO conventions served as the turning point in the legal backup for combating traffic and heritage smuggling. However, the enforcement power of UNESCO or its training and execution capacity is very limited. Physical management of heritage corresponds to others: national, private, academic, or nongovernmental entities.

In the transition from museum-oriented towards a community-oriented trend in stewardship, some important (but non-binding) UNESCO conventions in the late twentieth century changed the way cultural heritage is protected: The Hague in 1954 for cultural heritage in wartime, after World War II, and, in 1970, the convention on preventing the illicit traffic of cultural property. This latter convention would be crucial in the courts in determining which objects enriching the museums are legal or not. In the process, despite the conventions, cultural heritage becomes an ideal target in wartime for the psychological defeat of the enemy (Gerstenblith 2006; Marlowe 2011).

Later on, the UNESCO conventions of 1972 on *World Heritage*, both cultural and natural, and in 2003 on *Intangible Heritage* drastically improved the breath of the concept of cultural heritage (Francioni 2011). In addition, the 2001 Convention on the *Protection of the Underwater Cultural Heritage* was aimed at tackling the most important source of looting and generation of traffic of cultural heritage: the sunken ships along Mediterranean shores.

The process of acquisition of heritage will not stop with the laws promulgated by UNESCO. It is simply the means of the transactions that change, by increasing smuggling and illegal ways to ensure the continuing buildup of museum collections. The recent controversy between Italy and US museums is an example of the diversification of the ways to not stop such collecting drives.

Key Issues/Current Debates

Stewardship, Ownership, and Philanthropy

Since the creation of UNESCO and the concern over heritage, a strong debate has confronted museum managers and academics over the future directions of property of heritage (Merryman 1986). Under the premise that looting continues and museums are constantly adding to their collections, this debate evaluates the damage caused by this continuing will to keep the pace in artifact acquisition. This trend does not necessarily refer to less controversial acquisitions from in-country collections (which often are not exempt of controversy) but from different, often shady, proveniences, especially from overseas locations. A most memorable and enlightening debate in this regard is between the archaeologist Colin Renfrew (Brodie and Renfrew 2005; Renfrew 2010) and art historian John Boardman (Boardman 2006). These two experts do not agree on how tight the control on the trade of antiquities should be (high, according to Renfrew) nor on the primary role of museums should have for the protection of heritage (a leading role, according to Boardman).

The public exposed to this debate see as many benefits in the role of the museums and their *modus operandi* as they see in the strong will for a moratorium and zero tolerance to museum acquisitions, let alone looting and smuggling (see Bauer 2008). The fact that the latter two events continue to co-occur and are very hard to fight enhances the scenario of museums as ideal repositories of what is found in those same lootings – as they are "stewards" with the financial and physical means to secure the future of those artifacts. However, it is not that museums have a first option over the acquisition of heritage. Rather, there is a strong competition with market-driven forces between world museums and private collectors. The free-market rules of this trade are increasingly negative for cultural heritage as there is a sizeable financial gain to be obtained from the traffic in cultural heritage. The argument of museums as "stewards" and their commitment to the public are only good as long they are able to secure possession of the cultural heritage they deem important to their collections.

Therefore, museums and states that wish to be stewards of cultural heritage will do so by different means. This scenario depends, of course, on the legal system: some countries consider that heritage found on private property belongs to the owner, whereas another set of countries believes that all heritage resources found above and below ground belong to the state. On the one hand, private stewards curate existing heritage but are geared towards acquiring new holdings. On the other, states, often cash-strapped, are geared towards preventing and stopping traffic of cultural heritage, using the arguments of the 1970 UNESCO Convention and helped by bilateral agreements to reduce the smuggling of heritage. A considerable number of heritage resources have been returned to Peru, for example, thanks to its time-limited agreements with the United States.

Stewardship in the Realm of Cultural Heritage

Stewardship in the realm of cultural heritage is not as recognized today as is the role of state institutions, private foundations, or individuals in dealing with health, animal, or environmental issues as key factors in the current wave of sustainable projects in the social realm.

The essence of the concept of stewardship of antiquities (today regarded as heritage) has been at the core of the philosophy of museums and collectors since the nineteenth century. It is apparent that museums are not pursuing this image anymore. In the news, museums involved with legal issues of heritage ownership seem reluctant to increase their presence in the media. Again, in contrast with other institutions, while zoos have become centers for biodiversity, few museums have become centers for cultural dialogue (e.g.,

the Quai Branly museum in Paris advertises itself as a place "for dialogue between cultures"). This seems the case in ethnographic museums but not in art museums.

In the realm of cultural heritage, the concept of stewardship translates to different scenarios through time. First of all, it changes in the way the "object" of collection is referred to. This parallels the evolution of the clout, stance, and power of the traditional "steward," owner and caretaker of his/her prized possessions, and their dwindling power replaced by other rightful new actors. The "object" of collection then changes from "antiquities" in the nineteenth century, to "material culture" in the twentieth century, and ultimately to "cultural heritage" in the twenty-first century. These three historical assertions relate to how the artifacts and monuments are considered through time. Sites and burials are depleted of their artifacts to be housed in museums in the nineteenth century, while artifacts and skeletal remains are returned to native groups to be stewarded by their ancestors in the twenty-first century. There is a transition from a museum-oriented towards a community-oriented trend in stewardship, passing by a middle stage of broad academic studies of heritage in the twentieth century.

Stewardship in the Twenty-First Century

The role of a stewardship in the twenty-first century (fueled by a new philanthropic drive: the financial basis to stewardship strategies; see Henaff 2003) is as much a role of prime importance in the social sphere as it is a figure of an actor in strategic decisions regarding heritage or, more often, the environment or health issues. Stewardship has indeed diversified, and the fields of action range now from the closed encapsulated spaces of a museum to the open and dynamic areas of archaeological sites.

An intrinsic feature of the current concept of stewardship is that care of material or immaterial good is made despite not holding property rights of those goods. It is the moral concept of considering those goods valuable to society that leads to the investment and patronage in their preservation, integrity, and sustainability.

This is, therefore, a difficult subject because museums are stewards of their own holdings, obtained in property through the years by different means, including acquisitions from proveniences and means that may not have been well thought-out.

Due to this pattern of acquisitions, museums as stewards of cultural heritage have had important confrontations with national governments in the last decade. No museum or country is exempt of "reclamation" issues and often there are contradictions in the debate. For instance, while Turkey has claims over the Pergamon temple housed in Berlin, the Istanbul museum houses the Alexander sarcophagus from Lebanon. This is due to the geopolitics of the time when the Ottoman Empire had control over Lebanon (Waxman 2006). However, neither England nor Germany or the United States had such control over a region rich in cultural heritage (at least those that interested Western museums) as to warrant a "historical" explanation to the presence of those artifacts in their museums.

Issues with Stewardship in the Twenty-First Century

Two issues are especially important for stewardship as the safeguarding of cultural heritage and for the public dissemination of the importance of stewardship in today's society. These two issues concern, first, the strategies that museums will put in place as they ideally reduce their acquisition of cultural heritage that may be tainted by a shady looting provenience and, second, how stewardship is presented to the wider public by the new stewards, namely, communities of local populations interested in preserving and promoting their heritage.

Academic research is crucial in enhancing the public reach of heritage studies. While stewards aim to control (but do seldom manage) cultural heritage, it is the academic study of that cultural heritage from an art history to an anthropological perspective that are a value-added wealth to the monument, artifacts, or site in consideration. In academic studies, researchers do not own the object of study but do build its knowledge database that may or may not be used in strategies of

dissemination. It is not always clear to stewards that a good story to enhance the richness of heritage can come from academic sources. Quite often, the script comes from nationalistic or political sources (Cuno 2008). Academics therefore are not very proficient actors in the public process of creating a solid stewardship of cultural heritage.

On the contrary, it is rather the agenda of stewards that influences the acquisitions, research, and display that a museum might present to the public. What right do stewards have to direct the public display of cultural heritage, art in their eyes, and determine the outcome of that display? Might stewards overlook the wealth of information produced by academics? It would seem apparent that stewards have other values with which to measure their possessions, reflecting the aesthetics rather than the social frameworks directing their "contributions" to heritage. I have a specific case in mind: the recent and expensive renovation of the Roman wing at the Metropolitan Museum of Art that fails, at every level, to set the record straight on the decorative patterns in Roman architecture.

The second issue regards the stewardship drive undertaken by communities to preserve their own heritage, whether because it is inherited from their ancestors or because it lies in their current communal lands and they see it in a proprietarily way (as in the case of immigrated populations) (Stapp and Burney 2002; Welch et al. 2009). Is heritage less their concern because they are recent immigrants? Many attitudes by government agencies have alienated the local populations as they use the "ancestry" argument to lead to legal decisions.

Overall, however, the scenarios of communal concern over heritage do not necessarily imply a positive attitude or adequate management of their heritage. The most relevant point in this debate is that today stewardship requires a central concern for sustainability of the heritage not only for the community but for society at large. Believing that stewards have sole control and profit of that heritage has a negative impact, whereas consideration of usufruct of that heritage for society at large should be of prime concern. By the same token, it is apparent that museums use the concept of public usufruct in a much more convincing way.

In addition, to complicate the case of future growth of community stewardship, a set of internal factors may lead to these enthusiastic but sometimes disorganized scenarios of managing heritage: scarce education levels in local communities; limited knowledge of potential, risks, and obligations at managing heritage; and a too high political input into decision making procedures (Fennell 2008).

I underline the issue of poor risk management because it is not restricted to small, developing communities that wish to steward their heritage. Complex societies such as the case of the city of Rome face chaos in their stewardship role by not establishing long-term management plans to address in an organic manner the risks and needs of an overwhelmingly complex setting for cultural heritage.

Future Directions

Final Thoughts: Strategies in the Twenty-First Century

I suggest that museums may have to change their strategy of stewardship in future decades. Hopefully they will convince themselves that depleting burials and sites so as to have the artifacts adorning their displays or stacking their storerooms is poor policy. Certainly there is a wealth of heritage in storage rooms with which to create novel and attractive exhibits for years to come. What does the recent evidence show in this regard? If contentious arguments between sovereign nations and museums are any indication, perhaps the latter have not renounced to their old ways.

On the other hand, indigenous, native stewardship is on the rise – but with many caveats. The tendency of the last two decades is to have communities and nongovernmental organizations defend their heritage against encroachment of their lands. These communities have had a difficult time, however, dealing with governments, mainly for their lack of strategies to prove the existence of valuable and worthy heritage. This

scenario stems, of course, from ignorance in government circles. For instance to prove the existence of intangible heritage with no apparent commercial value is a difficult task. How to prove that a nomadic society which relies for their survival on large extensions of land for a hunting and gathering economy and that such strategy, that land, *is* their intangible heritage?

These questions are clearly important as we live today in a period where the property of cultural heritage (both in the material and intellectual realms) is fiercely debated. In this scenario, more often than not, societies reach the conclusion that artifacts are the property of the first nations, aboriginals, or natives. But this is not a given in young democratic societies. The number of social conflicts stemming from top-down unilateral decisions by governments impinging on local populations shows the high risk for conflict preserving their heritage (Alderman 2009). Governments are hardly steadfast stewards of the heritage in their very own country. Their attitude towards monumental heritage sites is often a reflection of those same market principles at as well.

The stewardship of the future will continue to develop at both the private level and the community level as both groups claim they are "stakeholders" to portions of heritage. However, the strategies they apply will need to change, not the least because both groups often will be stepping on each others' arenas. Both groups will still claim property over heritage. While aboriginal populations will be greatly favored by the legal baggage behind the issue of heritage claims, museums will persevere, as they do own heritage that is, arguably, beyond the control of native communities and countries of origin. Museums will not disappear, but their stewardship goals and strategies must change in these times of a greater awareness of cultural heritage and their original property.

Stoa

Erika Zimmermann Damer
Department of Classical Studies, University of Richmond, Richmond, VA, USA

Introduction

Stoa is an ancient Greek term applied to a type of long, narrow, free-standing building with a colonnaded façade. The stoa developed as an architectural form in Archaic Greece, and was most popular from the fifth through first centuries BCE. The stoa can be compared in its architectural impact with the colonnaded avenues typical of late Hellenistic and Roman cities and with the Roman *porticus*.

Definition

The stoa is a distinctly Greek architectural form of the portico that appears in a variety of forms from the Archaic (c. 650–480 BCE) through the Hellenistic periods (c. 323–50 BCE) and is found in sites throughout the Greek world. The simplest stoa was composed of three walls and a colonnaded front, yet this simplest form does not appear often in the archaeological record. Typically, the stoa form had a second inner colonnade that supported a ridge roof. Some stoas had small rooms behind the portico, some had two or more storeys, and some had projecting wings at either end, forming L or Pi shapes. The stoa had a variety of civic and religious functions: although the earliest examples appear in religious sanctuaries, the development of the stoa in the Classical period is linked to Athens, where stoas appeared at the margins of the Agora, the marketplace and civic center of the radical democracy. The characteristic appearance of a Hellenistic Agora came from the stoas that framed it. The stoa served a wide variety of purposes: at the sanctuary of Asklepios at Epidauros, the stoa served as the *abaton*, or sleeping dormitory, for the patients. In sanctuary spaces, stoas frequently housed dedications and offered shelter to priests and priestesses. In the Athenian Agora, stoas housed magistrates, functioned as public indoor space, held dining rooms, and served as display space for art and military spoils while the uniquely shaped South Stoa in Corinth served commercial functions. The growth of the stoa as a typical architectural feature of Greek cities mirrors sociopolitical transformations accompanying the rise of Greek urbanism (Aylward, 7552, *Urban Planning in the Greek World*). The stoa was thus an integral architectural building block of the Greek agora and sanctuary, central to Greek civic and religious life. The function and use of the stoa was multipurpose, but Vitruvius (*De arch*. 5.9.1) offers a basic ancient definition when he states that the stoa was a colonnaded building that serves to protect visitors from both the rain and the heat of the sun.

The stoa and the Greek temple share many architectural elements, but the monumentalized stoa, constructed of stone or marble, appears after the first all-marble Greek temples. In general, the building materials of the Greek stoa are more functional than those of the temple. The tendency in construction overall was to use less expensive

materials. Marble was frequently reserved for the façade, while walls were often built of local stone, mud brick, or rubble masonry (Coulton 1976: 142–143). In form, the stoa typically had a Doric exterior colonnade and an Ionic interior colonnade, thus forming a two-aisled interior. Multi-storeyed stoas also used the Doric and Ionic orders, along with interior half-columns with Pergamene capitals, and as time went on, a preference for the more elaborate use of the orders predominates. The single-storeyed form predominates, however.

As the building type developed, the columns began to be built in marble carrying a wooden entablature. The earliest stone porticos employed the Doric order, and this order dominates the archaeological record. The first monumental examples appear in the sixth century BCE, and are concentrated in Athens and Attica, where the radical democracy demanded new purpose-built architecture to support its governmental functions. The Athenian Agora, with its sequence of stoas built between the late Archaic and Hellenistic periods, provides a good example of the architectural form, and includes the first stoa with projecting wings, and one of the first stoas to incorporate rooms. In the Peloponnese, the South Stoa at Corinth and the Echo Stoa at Olympia are particularly noteworthy for their respective form and function. Ionia and the Hellenistic east present the fullest integration of the stoa into the Greek civic center, and forecast the development of the Roman use of the basilica and the *porticus* used to frame Roman *fora* and Roman colonial centers. The construction of a stoa was an expensive undertaking, and literary and epigraphic evidence demonstrate that most of the notable examples built in and after the fourth century BCE were funded by the Macedonian and Attalid dynasties established after the death of Alexander the Great (Schmidt-Dounas 1995: 23–52).

Key Issues/Current Debates/Future Directions/Examples

There is some debate as to whether Mycenaean porticos provided architectural origins for the classical Greek stoa. Origins in Near Eastern and Egyptian building types have also been suggested, but Coulton argues that the form has its origins in Archaic Greece (Coulton 1976: 18–23). In the Archaic period, the stoa became an autonomous structure, whose building components develop in parallel with temple architecture. Most known sixth-century stoas were small in dimension, and of lower architectural status than temples. In the sixth century, complete stone architecture became typical for temples, while only two known archaic stoas had stone entablatures. Most stoas of this period were found in sanctuaries, where they served as shelter for pilgrims and as places to display dedications. The two exceptions are the Royal Stoa, the earliest of the stoas in the Athenian Agora, and the stoa on the agora at Sikyon.

The earliest known example of the Greek stoa occurs at the sanctuary of Hera in Samos, and dates from the seventh century BCE. In form, the South Stoa at Samos was a long rectangular building, 70 m in length, with a back wall in rubble masonry, turning at either end, and two rows of wooden posts, one internal supporting the ridge roof, and 29 external columns forming the façade. In structure, the stoa was similar in size and shape to the cella of the Second Temple of Hera, and it anticipates the development of the Ionic order with the elements of base, capital, and dentils present (Coulton 1976: 27). In c. 478–470 BCE, the Athenians built an Ionic stoa at Delphi. This building incorporated the polygonal retaining wall of the Apollo Temple and was erected to display Athenian spoils from the Persian wars. The stoa used seven monolithic Ionic columns that bore a wooden entablature and carried an inscription on the stylobate.

The development of the stoa in the Classical period (c. 480–323 BCE) is exemplified by the series of stoas in the Doric order built around the Athenian Agora. Each was modest in construction but increased in size and in the sophistication of their interior design. These served to define the borders of the agora space: on the west by the Royal Stoa (c. 500 BCE) and the Stoa of Zeus (c. 430–420 BCE), and on the north by a row of herms, the Stoa of the Herms, and the Stoa Poikile (c. 475–460). When South Stoa I was built

Stoa, Fig. 1 Restored plan of the Athenian Agora in the second century BCE from Camp (1990: 27, Fig. 6)

(c. 430–420 BCE), it created a long uniform façade in the middle of the south side of the agora (Fig. 1).

The Athenian Agora, while it does not have the orthogonal corners of the Hellenistic agora, was nonetheless the first agora closely coordinated in design (Winter 2006: 54).

The Royal Stoa is the first stoa of the Agora and one of the earliest with a stone entablature. Dating from the mid-sixth century, it had a two-aisled interior, with stone columns in the Doric order on the façade and an inner Doric colonnade located behind every third outer column supporting lighter interior wooden beams, while the outer colonnade bore the stone entablature. The stoa was the headquarters for the *archon basileus*, the official in charge of religious matters and law in the democracy, and was where the laws of Solon were displayed. This building has been securely identified by Pausanias' description and by two inscribed bases, dedicated by king archons, found in situ on the building's steps (Camp 2001: 45). The Painted Stoa, or the Stoa Poikile, is located along the northern side of the Agora, and was built c. 475–460 BCE in the Doric order, with internal Ionic columns. The westernmost end of this stoa was discovered during excavations of the Athenian Agora in the mid-1990s,

and is currently under excavation by the American School of Classical Studies in Athens. This stoa was decorated with a series of panel paintings depicting mythological and historical scenes of Athenian military exploits, including the Greeks at Troy, an Amazonomachy, and the Battle of Marathon. The Painted Stoa was a public building without a particular function, open to everyone. The philosopher Zeno, who flourished c. 300 BCE, taught his followers, the Stoics, in the colonnade of this stoa (Camp 2001: 68–69).

The Stoa of Zeus Eleutherios, dated c. 430–420 BCE and built in the Doric order, is one of the first stoas to incorporate short projecting hexastyle wings. These wings were capped with triangular pediments crowned by sculptured acroteria. This stoa is also the first to use a three metope span, a structural device that reduced strain on the architrave. In this stoa, the architects made the frieze out of poros with inset marble metopes to further lighten the load on the columns. Here, too, the interior Ionic columns are spaced twice as far apart as the Doric columns, as will become standard in later stoas. The building is distinguished by the high quality of its workmanship, by the extensive use of marble, and by its dedication to a god. The stoa is the setting for three Socratic dialogues, and according to Pausanias was adorned with paintings celebrating the freedom the Greeks won at the Battle of Plataia, the final battle against the Persians on Greek soil. South Stoa I, a more inexpensive structure built c. 430–420 and dismantled for a replacement c. 100 BCE, featured a Doric colonnade and Ionic interior colonnade in front of 16 rooms. These rooms have off-center doors that allow the space to be identified as dining rooms equipped with couches. Coins found in situ point to the stoa's commercial function, and inscriptional evidence shows that the officials in charge of weights and measures worked here (Wycherley 1957: 46).

The stoas of the Athenian Agora show many of the most significant architectural developments of the stoa in the Classical period, but the stoa in Athens also served a variety of functions, and served to commemorate political and religious events within a secular building, housing magistrates and their governmental functions; displaying military spoils, decrees, and statues; offering ample public space for general recreation; and acting as dining spaces as well as serving commercial functions.

The Hellenistic period marked the appearance of much larger stoas used to define the space of the agora and the sanctuary. "The stoa is perhaps the most characteristic expression of the spirit of Hellenistic architecture, and determines the architectural form of the Hellenistic agora" (Winter 2006: 55). Some were very long, such as the winged stoa of Phillip II at Megalopolis, which was 155 m in length, or the Echo Stoa at Olympia. Begun in the third quarter of the fourth century, and completed by the mid-third century, the 100 m long Echo Hall at Olympia, located on the east side of the sanctuary, served to divide the Altis into distinct spaces. This stoa is remarkable for its lack of an interior colonnade and its wide roof span (9.97 m), with massive horizontal wooden beams running across the roof above each exterior Doric column. The Echo Hall was intended for viewing the great processions that passed in front of the building, and forecasts the importance of the view toward, as well as the view from, important buildings that is common in Hellenistic design (Winter 2006: 54). The stoa of Phillip II at Megalopolis is the largest and longest of the fourth-century stoas, and can be securely assigned to the years between 338 and 330 BCE, after Phillip II of Macedon's invasion of Laconia. In addition to the external Doric colonnade and projecting wings, this stoa unusually had two interior Ionic colonnades to balance the great length of the building.

The orthogonally aligned Hellenistic agoras gained their characteristic form through the framing devices of stoas. While the first Pi-shaped stoa was built at the sanctuary of Artemis at Brauron (c. 420–415 BCE), the most important of the Ionian stoas were found at Miletos, Priene, and Magnesia on the Maeander and were common throughout Asia Minor towns built on the Hippodamian model (Winter 2006: 56). In Ionia in Asia Minor especially, the agora was made into

a rectangular space through the use of L- or Pi-shaped stoas built on three sides of a rectangular open space with a street along the fourth. The effect was to create a continuous colonnaded façade. Such architectural framing also controlled pedestrian traffic, pacing, and access to agora spaces. The architecture of a colonnaded stoa encouraged ordered walking, where the regular spacing of columns regulates pedestrian pace and proposes an ideal rhythm that contrasted with the unregulated movement of pedestrian traffic in minor streets (Macdonald 1986: 48; Macaulay-Lewis 2011).

Height proved a design issue in stoas, utilitarian buildings where space could not be wasted. As stoas grew longer, the height of a single colonnade would tend to disappear into the vastness of the agora space (Winter 2006: 55). In order to create a more pleasing height-to-length ratio, architects adopted two-storey or multiple-storey designs, creating an exterior tall enough to overlook the rooms below. One of the largest known examples of two-storeyed design is the South Stoa at Corinth (c. 165 m in length), expanded in its second phase in the early third century BCE, with 33 shops with rear chambers and a unique water feature. The stoa was two-aisled, with 71 Doric columns outside and Ionic within; behind these columns was a row of 33 shops connected to a second row of storerooms featuring cold storage wells chilled with water from the Priene spring.

The use of two-storeyed stoas grew widespread in the fourth century, and in the Hellenistic period, we also have evidence for multi-storeyed stoas, many of which are associated with the Attalid dynasty at Pergamon. Large multi-storeyed stoas were placed along the terraces of hilly landscapes, and could be created either by placing a second portico above the main one at ground level, or by placing one or more storeys with basement rooms and porticos below the main portico to raise its floor to a higher ground level on the downhill side of a slope and to help retain the terraced ground level. The earliest of these is the East Stoa of the Athenian Asklepieion, built in the mid-fourth century BCE, where there were two superposed Doric colonnades on the façade of a two-aisled portico. The two-storeyed form appears to have developed here to meet the needs of those men and women worshipping and sleeping overnight in the stoa, but is later employed in buildings with a variety of functions.

In the Hellenistic period, there is a special category of Pergamene stoas, built during the reigns of Eumenes II (197–160 BCE) and Attalos II (160–139 BCE), which have distinctive features. Typically, the Pergamene style preferred a stoa with two storeys and two aisles, and made use of Doric columns on the lower façade and Ionic interior columns, while the upper storey used Ionic columns on the façade and interior double half-columns with palm capitals, supporting a mixed Doric-Ionic entablature (Coulton 1976: 66–72, 126–129). Athens has two representative Attalid stoas, the Stoa of Eumenes II and the Stoa of Attalos II, restored between 1953 and 1956 on the basis of Travlos' drawings by the American School of Classical Studies in Athens and now serving as the museum and warehouse for the Agora Excavations.

Eumenes II built a long stoa, just west of the theater of Dionysus on the south slope of the Acropolis, to shelter the thousands of people who attended the festival and theatrical events (Vitr. *De arch*. 5.9.1). This stoa was built into the steep south side of the Acropolis, so one of its most characteristic features is the large retaining wall and buttresses connected by semicircular arches still visible today. The stoa shows Pergamene style and also the direct influence of Pergamene architects in its construction. The palm capitals and cornice on the upper storey use gray Pergamene marble characterized by large crystalline inclusions, and the mason's marks on the blocks suggest that the stones were carved in Pergamon and imported to Athens after they had been worked. The Stoa of Attalos in the east side of the Athenian Agora was donated by Attalos II of Pergamon to the people of Athens (Thompson and Wycherley 1972: 78). This stoa is also in the Pergamene style but uses Athenian limestone and Attic marble. Like the South Stoa

at Corinth, this stoa had a row of 21 shops behind the colonnades on each storey, and served as the chief market building of the Agora in the Hellenistic period.

Large stoas were also built at the sanctuaries of Samothrace, Delphi, and Delos by Macedonian and Attalid dynasts, such as the Macedonian stoas of Antigonos II on the north side of the sanctuary of Apollo at Delos and of Phillip V on the southwestern corner of the same sanctuary. Comparable in the Hellenistic period are the multi-storeyed market halls exemplified at Aigai, Alinda, and Assos, where the agoras were formed on hillsides with artificial terracing (Dinsmoor 1975: 293). The South Stoa of the Agora at Assos in the Troad in Asia Minor, built in the mid-second century BCE, was one of the tallest buildings in the Greek world with a total height of five storeys, or 22 m, since it was built with two floors below the Agora ground level and two superposed porticos above ground level (Coulton 1976: 70).

Small two-storeyed stoas from late Hellenistic Delos, such as the L-shaped stoa of the Agora and the Agora of the Italians, may have inspired the two-storeyed porticos and arcades of late Republican and early Imperial Rome (Winter 2006: 56; on the Agora of the Italians, see Trümper 2008). Stoa building declines by the first century BCE. Although new stoas continued to be built throughout the Greek and Roman world, the Roman basilica and portico and the Hellenistic colonnaded avenues largely took over the function of the stoa. As the Roman Empire spread, architectural Romanization with its *fora*, framing basilica, and porticos tended to replace the Greek stoa in urban plazas (Macdonald 1986: 131). Colonnaded thoroughfares, including long porticos, are distinctive hallmarks of Hellenistic cities and Romanized ones both in the east and west of the Roman world.

Stone Structures in the Highlands of Uruguay

Moira Sotelo
Laboratory of Landscape Archaeology and Heritage (LAPPU), Archaeology Department/ School of Human and Educational Sciences – Associated Unit to the University Center of the Eastern Region (CURE), University of the Republic, Montevideo, Uruguay

State of Knowledge and Current Debates

Introduction

> . . .if it is not properly built, a rain comes and it all falls apart.
> Hugo (2014), a stonecutter from the north of Uruguay

Uruguayan highland landscapes are characterized by the presence of a variety of stone structures which are grouped according to their origin and construction technique. Some of them have an indigenous origin; some have a colonial origin (linked to the European settlement in America), and others are yet to be circumscribed in time. On this occasion, locally known indigenous constructions such as *cairnes* (cairns) and *vichaderos* (ring cairns) are presented. Stone, as well as earth, has been used since pre-colonial times for architectural purposes. This makes both cairns and ring cairns visible and permanent anthropic constructions that constitute a well-defined and delimited example of Uruguay's archaeological registry.

Until recent times, their study had not been a main topic in the agenda of Uruguayan scientific archaeology. As from 2010 to 2011, new research has been conducted, which has made their classification possible according to three main axes: (a) location, the kind of landscape chosen for their construction; (b) their spatial distribution, as there are some special features in the spatial configuration of clustered and isolated structures; and (c) their shape, as there is a standardization in the morphology, construction techniques, and size. Current work delves into when and why they were built.

What Do They Look Like?

According to their morphology, these structures can be classified as follows:

- **Mounds** are compact, semispherical structures that at times tend to be cone-shaped. Their base is circular to elliptical and at times rather large. Their size ranges from 2 to 6 m of diameter and is usually less than 1 m tall (Figs. 1 and 2). In Uruguayan literature, these stone mounds are often referred to as "cairnes" (Figueira 1898). In this text, the term *cairn* refers to a broad category that comprises stone mound structures used for different purposes.
- **Rings** are ring-shaped wall structures of circular base. Sizes vary between 6 and 10 m of diameter and 1 m of height (Fig. 3). These circular enclosures are locally known as "vichaderos." For this work, in a broad sense and for easier reference, they will be referred to as *ring cairns*.
- Some authors (e.g., Palermo et al. 2004) also use the word "cairne" to refer to conical/pyramidal structures of up to 2 m of height with a construction technique which is different from the previous two (Fig. 4). These structures have not been studied and require specific research. Within the **cone** category, there is a wide variety of constructions, and their exact genesis is yet to be determined. The main discussion revolves around their origin – whether indigenous or European.

Where Are They Found?

In Uruguay, cairns and ring cairns are found in the highlands of the northern-central and eastern regions of the country (Fig. 5). Despite the country's lack of high elevations, the singularity of this territory lies in the almost uninterrupted presence of long undulations that stand in the way of several waterways, which constitutes a varied landscape. This sequence of ranges and hills

Moira Sotelo is a National Agency for Research and Innovation (ANII – Uruguay) Pre-doctoral researcher, fellow at the University of Seville (Spain).

Stone Structures in the Highlands of Uruguay, Fig. 1 Cairn on the Charrúa Hill (Department of Tacuarembó, Uruguay)

Stone Structures in the Highlands of Uruguay, Fig. 2 Cairn on the Aguirre Range (Department of Rocha, Uruguay). (Picture: Pablo La Rosa – LAPPU Archive)

creates a dense hydrographic mesh composed of rivers and streams of permanent flow and innumerable creeks and sporadic waterways. Within this context, ranges (locally known as "cuchillas" or "sierras") and hills ("cerros" in Spanish) are the most typical Uruguayan topographic features, with heights between 150 and 500 MAMSL. The indigenous populations that built the cairns chose these high and stable places for their construction. These locations are characterized by their unique beauty and a high heritage value, as well as by their excellent visibility to monitor the surrounding landscape.

So far 60 references are made (both from bibliography and from archaeological survey) to places where cairns and/or ring cairns are located, which coincide with those portions of the land where hills and ranges predominate (Fig. 5) (Sotelo 2012, 2014). Fifteen of these places have been surveyed, and a total of 91 structures

(76 cairns and 15 ring cairns) have been identified (Table 1).

How Are They Made?

Cairns and ring cairns are stone structures built using a dry stone construction technique in which stone blocks are manually placed. Rough blocks are laid in a juxtaposed, imbricated fashion (emulating fish scales) without using mortar or any other kind of bonding material. The friction between the interlocking blocks distributes pressure, enhancing the stability of the structure while preventing it from collapsing. Consecutive layers are bound in such a way that they create ring- and mound-shaped structures.

Blocks available in the surrounding environment were chosen for their construction, of 20–50 cm of size (some even larger) that can

usually be carried by one person or a few more people. Stones were chosen one by one so as to obtain an overall stable structure, using blocks in good condition (that were not eroded or cracked) and according to their complexion, density, hardness, and durability. In some cases, blocks were carved, or cracked surfaces were taken advantage of so as to accomplish ideal shape and placement. Structures were usually built on rocky outcrops, which is why it was often necessary to level the ground by quarrying it.

In the Aguirre Range, in the Department of Rocha (Fig. 9), two structures were archaeologically surveyed by using geometric registry, digging, and restitution: the Mario Chafalote mound (MCH) and the Ester Chafalote ring (ECH) (Sotelo and Gianotti 2015–2016). (Works conducted on the Aguirre Range and the Chafalote Valley were co-directed by Dr. Camila Gianotti and the author of this entry, Moira Sotelo, and funded by the R&D project: *Landscapes built since pre-colonial times. Settlement logics and use of the environment by indigenous populations in the highland-lowland transition*, of the Committee of Scientific Research of the University of the Republic (Uruguay). Such work is also part of Moira Sotelo's doctoral thesis.) The documentation and analysis strategy merged diverse geospatial technologies (geo-location digital records with DGPS, Total Station, GIS, and photogrammetric records) so as to approach two different spatial scales: a medium scale, defined by the location and position of the sites, which aims at determining the topography, position, and morphology of the structures, and a small high-frequency topographic scale, which contemplated

Stone Structures in the Highlands of Uruguay, Fig. 5 (continued)

construction features and a detailed record of the elements that compose it. Data processing permitted the elaboration of digital models of the land, photogrammetric models, plane measurements of the structures and their construction features, stratigraphic sections, and spatial distribution of archaeological materials located at the planned excavation sites (Machado et al. 2016).

The MCH site is located on a hilltop at 220 MAMSL, one of the highest points in the Aguirre Range, where a stone mound was identified. It was found at the highest point of the top in a privileged location, dominating the surrounding landscape and providing a visual control of 360°. The structure consists of a stone and earth mound built on a rocky outcrop (used as part of the structure), covered by an outer shell made of imbricated stone blocks. Geological studies have shown that the blocks used in the masonry are ignimbrite blocks found in the range (Chiglino

		3 small cones	
Cementerio hill			
5 cairns			
2 ring cairns			

2016), which were combined with smaller quartz and phyllite blocks to make the outer shell.

Indigenous tools found at the MCH excavation site were made of raw materials different from those used in construction: a broken *bolas* ball made of basalt (not available in the area), instruments, cores, and flakes made of quartz and tuff (available in the area). The lack of bone remains in the excavated area resulted in the implementation of a strategy that searched for signs of hydroxyapatite in the sediments. The results of the analyses showed that no burials ever took place (Rodríguez 2016). The structure was dated at around 1700 of our era (230 ± 30 BP. Beta – 442,081) (Sotelo and Gianotti 2015–2016).

The ECH site is located at 140 MAMSL on a ridge at the northern end of the Aguirre Range. A ring-shaped structure is found on the slope with a NE-SE arch view of 180°. The ring is composed of medium-sized, flattened, semi-rounded stones of local ignimbrite, laid out in a shell-like fashion and creating an outer ring. This shell is built directly on the outcrop and reinforced toward the slope by retaining walls placed under the outer row of stones. To layer the larger blocks toward the slope, smaller stones (rubble and chocks) were used, wedging the blocks and filling the holes in between the rocks. On the NEbN side of the structure, there is a row of rounded, flattened, apparently fallen stones of around 1 m of diameter, which might have been driven into the ground (Fig. 6). At the excavation site, tuff and quartz cores and flakes from the range and its surroundings were found. Again, human remains were not found.

How Are They Arranged? How Do They Relate with Each Other?

There are different ways in which structures are spatially distributed and arranged with each other. In some cases, they appear isolated, whereas they are sometimes found in clusters. Works carried out so far allow us to propose three categories or patterns of placement and configuration: clustered, disperse, and single. These categories are likely to be modified or broadened as further research is conducted.

The **clustered pattern** consists of clusters of structures in which two different displays are observed: (i) clusters in conspicuous hills and (ii) rows in hillocks.

i. The first clusters are located on hills that stand out in the landscape; they are conspicuous and

Stone Structures in the Highlands of Uruguay, Fig. 6 Planimetrics of the Ester Chafalote Site (ECH, Aguirre Range, (Department of Rocha, Uruguay) done with georeferenced Total Station as part of an R&D project named *Landscapes built since pre-colonial times. Settlement logics and use of the environment by indigenous populations in the highland-lowland transition* (CSIC/UdelaR)

prominent and have elliptical, flattened tops. The structures that have been identified so far through archaeological survey have 1 or 2 rings, between 3 and 20 mounds, and, occasionally, walls that interconnect these structures. They crown the hilltops in open and flat areas and have a wide visibility spectrum (of up to 360°). The inward spatial

S

Stone Structures in the Highlands of Uruguay, Fig. 7 Charrúa Hill, Department of Tacuarembó, Uruguay. The hill reaches the 280 MAMSL and has a 360° view over its surroundings. A cluster of nine mounds, one ring, and some walls are found at the top. On the east side of the hilltop there is a sub-cluster with one ring and eight mounds. On the opposite side, there are at least three more mounds and a long wall. Native vegetation at the top makes the full observation of the structure difficult, and some parts are likely to remain hidden under the grass. Archaeological remains such as bolas, racloirs, and a projectile point found at the base of the hill are kept at the Indian and Gaucho Museum and were also found by Omar Michoelsson. (Picture and drawing: Sebastián Santana – LAPPU Archive)

distribution of the cluster has different configurations: an open *U* shape facing southeast, sub-clusters, and rows (Figs. 7 and 8).

ii. Rows are another way in which clusters are distributed. This configuration implies that structures are found in lines, a few meters apart from each other at roughly regular intervals. These structures seem to have a conic rather than a mound-like shape, with a rather small base. This type of configuration has not been studied in detail, and its identification results from preliminary field observation.

The **single pattern** is made of a single structure located at the top of a hill or hillock, more or less isolated from other hill formations. They may be a ring or a mound with the same average dimensions of the other structures present in cluster formations.

In the **disperse pattern**, structures are found along the many hilltops that compose long ranges and have a wider structure diversity. Not only rings and mounds are present but also cones, four-sided structures of piledriven stones, pens, and walls built in colonial times, among others. Cairns and ring cairns are usually located along the highest points of the watersheds (Figs. 9 and 10).

High Archaeological Landscapes: The Hill Range as a Space Built by Uruguayan Indigenous Populations

What Were They Built and Used for?

Why indigenous populations built cairns and ring cairns is yet to be determined. However, archaeological and historical research makes it possible to discuss some hypotheses regarding their use and their true origin.

After the Europeans arrived to the River Plate in the early sixteenth century and until the first decades of the nineteenth century, a number of manuscripts and maps on the newly found territories were written and drawn. Sailors, explorers, journalists, priests, military, cartographers, colonial officers, and naturalists, among others, witnessed the lives of the hunters and gatherers who lived in the area. Until the second half of the seventeenth century, most of the documentation

Stone Structures in the Highlands of Uruguay, Fig. 8 The Minuane Hill and a sketch of a cluster of structures built on its flat hilltop (Department of Rivera, Uruguay). It has an altitude of 360 MAMSL and a 360° view over its surroundings. The cluster consists of nine stone structures (two rings and seven mounds) which form a horseshoe that opens toward the southeast, with four inward sub-clusters. Two flakes were found on the surface during archaeological survey at the site

was written near coastal areas – and not so much inland – especially at the mouths of the Paraná and Uruguay rivers. When reports on the inner lands became more abundant, local populations had already been massively affected by illnesses brought from Europe and by the migration of indigenous populations who attempted to prevent their women and children from being kidnapped (Bracco 2004, 2013). In Uruguay, the advance of European settlers across the territory was based on a strategy known as "settler colonialism." This kind of colonialism was not based on capital gain relying on the exploitation of native workers in conditions of slavery or semi-slavery (as was the case of early colonialism in areas such as the Andes or Mesoamerica). When indigenous populations were banished or exterminated through planned campaigns, the very settlers were in charge of exploiting the conquered lands. This context brought extremely negative consequences for native groups such as the loss of their practices, concepts, and traditions, making their preservation very difficult (Verdesio 2014).

Based on documentation dating from colonial times, it has been often said that cairns and ring cairns would be the result of local burial traditions before European settlement (Figueira 1898; Femenías 1983; Sotelo 2014). According to these sources, indigenous populations had the custom of burying their dead and then covering them with stones, especially on hilltops and their surroundings. It is in this sense that the word "cairn" is often used in Spanish to refer to burial mounds.

Cairns are locally known as "cairnes," a curious Spanish form for "cairn" (Sotelo and Soler 2015). It may have first appeared during Charles Darwin's journey across South America in 1832 on board of his ship, the *HMS Beagle*. While visiting the *Sierra de las Ánimas* (Range of

Stone Structures in the Highlands of Uruguay, Fig. 9 Map with the location of cairns on the Aguirre Range in the Department of Rocha, Uruguay. Structures in a disperse pattern were found at the site, which was designated as an experimental area to conduct further site and intra-site research on cairns at a local scale through the application of different methodologies and techniques. Along this range, a number of structures were identified: a cone, three conic mounds, two rectangular structures of piledriven stones, at least four mounds (MCH and others), a ring (ECH), and three stone stacks that fill a crack in the outcrop with small- and middle-sized stones of sharp gravel (among which a quartz core was found on the surface)

Souls) in the Department of Maldonado, Darwin (1921 [1832]) wrote in his travel log about the finding of stone piles, which he found similar to the cairns built in the British Isles. A local guide who walked with him along the range mentioned that they were used by the natives to bury their dead. Stone piles found on hilltops are linked to indigenous graves both in documents and oral accounts of the time.

In Darwin's words:

> At the top of the hill range we found piled stones in different locations, which had clearly been there for many years. My partner claimed that they had been built long ago by the Indians. The piles were similar, though at a smaller scale, to those often found in Wales. Seeking to leave behind a reminder of a specific event at the highest point in the surroundings seems to be a universal passion among the human race. There are currently no Indians of any species, either civilized or not, in this part of the province... Darwin. (1921[1832]: 68–69)

So far, there are very few and inaccurate references to the presence of human remains linked to these structures. J.J. Figueira (1965) wrote, without giving further details, that the only objects found inside and near these structures are bolas and parts of human remains. As for Femenías (1983), he mentioned that very few materials were found near these "piles" and that in the departments of Salto and Paysandú, some

Stone Structures in the Highlands of Uruguay, Fig. 10 Panoramic view toward the east side of the Aguirre Range in the Department of Rocha (Uruguay). Archaeological works carried out in Laguna Castillos identified 30 monticular structures of earth (cerritos) of which two were excavated Cráneo Marcado and Guardia del Monte (Capdepont 2006; Pintos 1999). (Picture: Pablo La Rosa – LAPPU Archive)

reference is made to bolas and human remains by the side of these structures, yet their features have not been detailed, and therefore such information must be carefully considered. Archaeological excavations carried out at the MCH mound and the ECH ring were unable to find human or animal bone remains (Sotelo and Gianotti 2015–2016) or any other sign that might indicate earlier bone presence. The excavation carried out at the Horqueta ring cairn was also unable to find bone materials.

However, the fragmented piece of bolas found at the excavation of MCH site is contextualized as an object that, apart from being used for hunting and for war, had symbolic connotations in the everyday lives of hunters and gatherers. Bolas are part of a group of objects with a strong symbolic meaning in the beliefs, myths, oral accounts, customs, and rites of these populations and are sometimes found in funerary contexts of the Pampas (see Bonomo 2006).

As per ethnographic sources, a first reference to the use of stones in burials was found in 1687: a description by the Jesuit Francisco Jarque of the native Guenoa nation, located on the Uruguay River. Jarque (1687, Chap. 23) accounted that this indigenous population buried their dead under big stones or logs and that when they moved, they carried along the bones of their dead. Afterward, references to stone-made Indian tombs become frequent (Femenías 1983; Sotelo 2014), such as in the diaries and travel logs written by the members of the Spain-Portugal Boundary Demarcation Commission. In the 1750s, and again in the 1780s, these two crowns commanded mapping expeditions to demark the boundaries of their colonies in the American continent, hoping to settle their disputes on these boundaries. In many travel logs and diaries, "stone mounds" are mentioned by members of the Commission, found at the highest points while measuring the land. Also, they provided detailed information on their location (Oyarvide 1865 [1784]; Alvear y Ponce de León 1784 of the Spanish parties; Saldanha 1929 [1786–1787] of the Portuguese court). While Alvear y Ponce de León was traveling around the Arequita Range and the Penitente hills, he wrote: "On top of almost every hill you can still find today many tombs of Indian pagans. They basically consist of an enclosure of stones scattered within a diameter of 7 feet and are between 4 and 6 feet high. This seems to be a general Indian tradition, as described by Mr. Antonio de Ulloa during his expedition to measure a degree of meridian arc" (Alvear and Ponce de León 1784 s.p.).

Another construable use according to these sources is related to the elevations and structures as places of faith and spiritual and religious Indian practices (Femenías 1983). Rituals and

ceremonies such as fasting, the worship of deities and of the dead, as well as shamanism, among others, were celebrated. The documents and cartography written by the Jesuit missionaries of the Society of Jesus are a good example. They arrived in South America searching for a "spiritual conquest" and the "salvation of souls and the establishment of Christian culture" among the peoples of the New World (Furlong 1984 [1936]: 22, 26). These are some of the accounts of that time:

> On the Yaceguá hill, Guenoa pagans celebrate their funerals; they bring their dead from many leagues away to be buried.
>
> On the Ybití María hill, Guenoa pagans formally become sorcerers; there they gather, they make their quivers, they pierce themselves, drill their bodies and do evil things until the very devil appears at the top of the hill. The Ybití María hill is located at the headwaters of the Yarapei River. (B. Nussdorffer 1754 in Furlong 1936: 80–81)

Altogether, documents refer to the use of stones as an indigenous custom to bury the dead and as eventual places for rituals. However, no records have been found on anyone having ever directly witnessed interment ceremonies or rituals of any kind.

Colonial documents also describe the systematic activity of sentinels and spies in enemy territory as part of the military and territorial strategies back in those days (López Mazz and Bracco 2010). In geographical terms, the locations where the indigenous populations built stone structures are areas of visual land control used for surveillance and to monitor animal flocks for hunting as well as the arrival of people, among others. In the area of the River Plate (Argentina and Uruguay), the term *vichar*, according to the Royal Spanish Academy (RAE 2012), means "to observe," "to invigilate," and "to watch while hiding." Hence, *vichaderos* (literally watching points in Spanish) are high places used to watch and monitor the land.

An interesting aspect related to the research of stone structures in Uruguay is the toponymy of the places where they are found. For instance, archaeological surveys resulted in the finding of large clusters of cairns and ring cairns at the top of the Minuano and Charrúa hills (current names used in national cartography). According to colonial documents, the Guenoa-Minuane and Charrúa peoples were the main native nations in these lands at the time of European settlement. Likewise, the most important clusters of structures that appear in the records – with clusters of up to 200 structures – are found on the Betete and Tupambaé hills, named like two Minuane caciques (Figueira 1958). In this sense, current names for various landforms where several stone monuments can be observed derive from indigenous words. However, how far back in time these terms go still remains unknown. On the other hand, there are hills with cairns whose names are associated to an early function, such as the Cerro Cementerio (Cemetery hill) and the Sierra de la Sepultura (Burial Range), clearly associated to death, or even hills like the Centinela (Sentinel) and the Vichadero (Watching Point), referring to the surveillance and monitoring over the territory.

By colonial times, after the mid-nineteenth century (with severely decimated and transformed populations) and during the twentieth century, *criollos* (European descendants) and Europeans with an interest in pre-colonial history began to tour around the country and record their archaeological findings. In 1882, Julio Piquet published on a newspaper an article on his expedition with José H. Figueira's to the Tupambaé hill in the Department of Maldonado. He pointed out that stone mounds covered the hilltop and that there were no fewer than 200 of them. "[. . .] We got off and began to demolish one of those mysterious tombs. We destroyed 6 or 8. . .but found nothing. . ., nothing at all" (Piquet 1882 in Figueira 1958: 16).

"At the tops and on the sides of the highest hills and hillocks of Uruguay, piles of rough stones can often be found. They are rounded or cone-shaped, erected by men and known as "Indian graves," as they were presumably built by aboriginal peoples for the same purpose of their name. Such mounds have a round or elliptical base and are rather small, with a maximum of 2–3 m of diameter and between 50 cm and 1 m of height. Some of these structures lie directly on the ground, while others lie on metamorphic rock, which makes up the majority of our hills and ranges. These mounds

may appear isolated or in clusters. The most important ones that I have seen are found on the Tupambaé hill [...], around 200 stone piles which are regularly distributed in rows". – José H. Figueira (Figueira 1898: 309–310.).

The press of that time also echoed and began to publish the new archaeological findings. In the city of San Fructuoso (nowadays Tacuarembó), the *El Noticioso* newspaper published in 1898 an article titled "The cairns of Tacuarembó" (El Noticioso 1898).

By Whom and When Were They Built?

One of the most interesting aspects regarding cairns and ring cairns is linked to their builders and to the time when they were built. Once again, the arguments for debate are provided by archaeological and historical research. There is a spatial correlation between the areas described in documents and the places where the archaeological sites with stone structures were actually found. In particular, there is a spatial coincidence between the area where the structures are found according to the records (later on corroborated through archaeological survey) and the territory inhabited by Guenoa-Minuane populations in colonial times (Acosta and Lara 1989; López Mazz and Bracco 2010). It is worth remembering the examples given by Jarque in 1687 (Guenoa burials with stones) or Nussdorffer in 1754 (Guenoa burials and rituals on hills).

Guenoa-Minuane settlement in the Uruguayan territory between the seventeenth and nineteenth centuries was well recorded in colonial documents, in which a pattern in the lands they populated and the changes that took place for two centuries were observed. In some cases, occupation is incidental and is related to a passing group. In other cases, there is evidence of large settlements with a number of the *toldos* (Indian tents) on lands that, according to chroniclers, were used and belonged to the Minuanes. Also, places where they used to fish, bury their dead, and perform rituals are mentioned. These Minuane communities were led by respectable caciques and are scattered throughout the territory, yet in constant movement and contact with other communities from the region to whom they are related and with whom they share alliances and other kinds of bonds (López Mazz and Bracco 2010).

The territory occupied by the Minuanes was reconstructed based on the analysis of maps and documents of that time. The limit toward the east is the Atlantic Ocean. These ethnohistoric studies show, among the many places where they are found, the presence of Guenoa-Minuane *tolderías* (group of *toldos*) between the area of Castillos Lagoon and the Chafalote Creek around the seventeenth and eighteenth centuries (López Mazz and Bracco 2010) (Fig. 9). The Minuanes are "the nation of savage Indians who dwell in that region" or, more accurately, "who have long lived in the area of Castillos" (General Archive of the Indies, Charcas 221. The city of Buenos Aires to the King 1721, in López Mazz and Bracco 2010: 104).

In 1750, the areas of Chafalote Creek and Castillos are still occupied by several communities, and the Castillos Lagoon is identified as a field where the Minuanes hunt deer (López Mazz and Bracco 2010):

> To the Governor and Captain General. Dear Sir. The officer of the Maldonado Guard informed me on a letter dated the 1st day of this month that, having a party set out to scout the fields within some 25 or 30 leagues away, and having spotted a rider with some horses ahead, believing him to be someone on his way to Rio Grande they followed him, unable to see anything else due to smoke coming from burning grass, and unexpectedly ran into a group of Indian tents. He could not distinguish to which nation they belong, but they are a great many, located between the Chafalote Creek and Castillos Grande. Our party being too few and they being too many and armed, they continued to steal the supplies from a cart. Our men finally retreated, leaving behind 13 royal horses (...) and fearing for their lives. This location becomes a regular seasonal Minuane settlement due to the large number of deer available for hunting, where also rebel tapes usually gather, and we do not know whether they might be fugitives of the last battle near the removal. . ..(General Archive of the Nation [Argentina] Room IX File 1(2–1–4); File 2 (2–1–5). Francisco Gorriti log, in Martínez Rovira 1982)

The excavated cairn MCH, dated c. 1700 of our era, is located at exactly 1000 m from the Chafalote Creek, an area which was evidently populated at that time by Guenoa-Minuane Indians. The discussion focuses on the following

question: Are we standing in front of a landscape built by Guenoa-Minuanes between the seventeenth and eighteenth century?

Final Discussion: Structures That Semanticize the Landscape and Configure the Territory

The sociocultural phenomenon of building cairns and ring cairns has an underlying spatial and symbolic rationality which is materialized in this kind of structures. The spatial logics appear through some consistencies in the location, distribution, and shapes: topography as a key factor in the choice of a certain location, the repetition of spatial configurations at a territorial and intra-site scale (clustered, disperse, and single), and a standardization of forms (mounds, cones, or rings), sizes, and types of rocks, with people who specialized in the construction techniques as well as in how and where to place them.

Cairns and ring cairns, together with their geographical surroundings at the hilltops, probably acted as structuring elements of the land. These elements were created by a certain culture and possess a special significance for those who built it. They may be regarded as socially active spatial symbols (Criado Boado 1991), considering that societies without a written language tend to take symbolic ownership of certain places which usually stand out in the landscape and have a cultural spatial significance (Ingold 1986). In these groups without a writing system, memory resides in oral accounts and material culture, particularly the one that best resists the deterioration caused by the course of time (García Sanjuán 2008). Indigenous populations might have turned the tops of several hills and ranges into places for rituals, land markers, or places for land surveillance. Further research on the different uses linked to the different shapes is still needed, but they are in fact evidence of something that has been materialized, of a system of symbols by which beliefs, concepts, and/or events are represented. The fact that some structures were used as tombs does not rule out the possibility of their being used for other purposes, even for specific occasions.

Further dating in order to obtain a more accurate chronology – when were the structures built and when did their construction cease – is a key aspect in the research of cairns and ring cairns. The reports written by European settlers as well as the dating of the MCH structure (mainly around the seventeenth and eighteenth centuries) dated these structures at a specific historic time in which the Charrúa and Guenoa-Minuane indigenous resistance struggled to survive. European conquest and colonization processes in the current Uruguayan territory led to the extermination of the indigenous groups as communities and the slaughter of much of their population. However, the genocide was not absolute. Those who survived either scattered or blended with the colonial society (Cabrera Pérez and Barreto 2006; Cabrera 2011). Eventually, the official history of Uruguay was written as a country without Indians, claiming the European origin of its society. Nowadays, ethnic minorities are reclaiming their indigenous roots and promoting the search and acknowledgement of the Charrúa culture (Verdesio 2014). Genetic studies (Sans et al. 1997) show that indigenous – and Afro – populations are a component to be considered when analyzing the configuration of the Uruguayan population. Archaeology and the studies of indigenous stone architecture focus at the moment on the context of social transformation of colonial times and are destined to make contributions through the archaeological record of those who wrote not on paper but on the landscape.

Introduction

Although strictly speaking the concept of *artifact* refers to what is actually manufactured (e.g., by flaking or grinding), in archaeology the term *stone artifact* commonly refers to any stones that are made, modified, or used by humans (other primates also make and use artifacts; see Mercader et al. 2007). The by-products of manufacture are often also called artifacts in the sense that humans produced them. *Stone tools* are usually defined as those artifacts that actually have evidence of use. For reliable identification of archaeological stone tools and determination of specific functions, analysts rely on *multiple lines of evidence* that might include tool design, usewear, residues, breakage patterns, hafting traces, and archaeological context. Ethnographic and experimental evidence is also important. Usewear and residue analyses have the potential to provide a reliable basis for reconstructing and evaluating the nature of prehistoric tasks, resource utilization, and settlement history.

Definition

Residues in this context generally refer to materials that are transferred and adhere to implements in the course of use or preparation for use. We are particularly interested in residues that are transferred to stone tools (Briuer 1976;

Hayden 1979; Loy 1993). Of particular interest is the transfer of residues linked with a specific task (e.g., harvesting cereals or hunting) or processing a particular material (e.g., woodworking or grinding seeds). However, some residues are unrelated to utilization and may reflect incidental contact, burial processes, or even modern contaminants. Some tool residues can survive intact on artifacts for millions of years, while others may deteriorate rapidly and undergo chemical changes depending on their structure and specific taphonomic conditions. Consequently, specific methods of extraction, identification, and analysis have been developed for particular conditions, particular artifact types (e.g., ceramics), and specific kinds of residues (Evershed et al. 1992; Pollard and Heron 1996). The principles of residue analysis are based on the identification of diagnostic microfossils, chemical signatures, atomic structure, and genetic composition, as well as of other properties.

Usewear (or "use-wear") refers to the wear on the edges and surfaces of an implement that is linked with its utilization (Odell 2004). *Microwear studies* sometimes refer to a particular approach that employs metallographic microscopes at high magnification, especially (but not exclusively) aiming to observe and interpret polishes on stone tools (see below). *Traceology* is a term that may refer to the study of any traces (whether residues or surface alterations), usually in the context of tool use, and can be synonymous with microwear studies. However, these terms are often used synonymously to refer to surface modifications that arise during use, hafting, handling, and storage. Some forms of usewear may incorporate or absorb residues within surface layers, providing a mixture of additive residue and usewear traces. The general principles of usewear analysis are experimentally based and derived from fracture mechanics, tribology, and related sciences. While potentially applicable to all material classes (including artifacts made of wood, bone, stone, glass, shell, antler, ceramic and metal), specific methods and interpretive rules have been developed for particular tool materials (e.g., flint).

Key Issues/Current Debates/Future Directions/Examples

The main forms of usewear on flaked stone tools include scarring, striations, edge rounding, smoothing and polish, and bevelling (Hayden 1979; Kamminga 1982). Each form of usewear provides evidence of function but is rarely sufficient on its own to reconstruct particular tasks. Striations, for example, clearly indicate directionality or motion of tool use but are not diagnostic on their own of particular processed materials such as wood, shell, or skin. On the other hand, hafted flint flakes used for hide scraping sustain highly distinctive edge rounding along with a low incidence of edge scarring and abundant striations perpendicular to the utilized working edge.

The fracture mechanics of flaking indicate that particular properties of scars (e.g., initiation, termination type, orientation, and size) are linked with force application, edge morphology, and the nature of materials worked. For example, low-angled tool edges used to cut even soft tissue are particularly prone to produce scars with bending initiations and axial terminations. Bending scars on low-angled edges like this are rarely diagnostic of particular raw materials. However, low-angled tool edges used to saw bone sustain a highly distinctive bending scar pattern with crushed, rounded prominences, and uniform scar spacing (Kamminga 1982). Particular functional tool types known ethnographically sometimes sustain diagnostic scarring in association with other forms of usewear. For example, stone points used as drills sustain characteristically angled scars oriented at right angles to the circular drilling motion. Stone arrow and spear tips sometimes sustain burin-like impact fractures that, in conjunction with other features (e.g., microscopic striations/polish alignments), may be crucial in determining a projectile's function.

Polish on flint tools has been studied extensively and can be a diagnostic indicator of material worked (e.g., van Gijn 2010). Stone segments hafted as sickle blades sustain a highly characteristic gloss that indicates highly siliceous plants. However, particular forms of usewear are not studied in isolation but in combination with

other forms of usewear, other traces of use (e.g., residues), and other lines of evidence such as tool design, breakage, and consideration of the archaeological context.

Grinding and pounding implements (upper and lower stones) sustain surface modifications that include smoothing, striations, and pitting rather than the edge damage that is found on flaked stone tools. Crushing and grinding minerals (e.g., ochre), plants, and animal tissue force residues (including liquids, chemical compounds, and particles) into cracks and imperfections on the tool surfaces. Some grinding stones are selected for the composition of their cemented particles and their suitability for processing particular foods (e.g., grass seeds). Other stones are selected for their toughness and suitability for edge ground tools. Grinding stones and ground stone implements (like axes) with a porous surface or deep cracks provide, under suitable preservation conditions, a reservoir of deeply impacted and absorbed residues related to utilization.

Haft traces can be indicative of particular handles and tool function (Rots 2010). Experiments show that combinations of bindings, sockets, and adhesives affect the type, location, and abundance of scars, striations, and polish.

Residues in archaeology are the minute remains that are transferred to an artifact. The presence of a residue follows Locard's exchange principle which states "with contact between two items, there will be an exchange" (Thornton 1997). There is a range of residues currently studied by archaeologists, chemists, and archaeometrists. These can include microfossils, fibers, scales, particles, pigments, traces, amorphous residues, and biomolecules. The microfossils studied are predominantly plant microfossils represented by pollen, phytoliths, starch grains, and other inorganic crystals (e.g., schlerieds, raphides, and druzes). The fibers will include natural plant fibers (e.g., cellulose), animal fibers (e.g., collagen and hair), insect fibers (e.g., silk), and historical synthetic fibers. Scales can be observed from fish and reptiles in residues. Particles can include organic particles (e.g., charcoal) or inorganic particles (e.g., metals) which can be found in a residue to indicate metal working. Pigments can also be inorganic or organic but are predominantly inorganic in the archaeological record (e.g., ochre and cinnabar), while traces can include tissues and cells from plants or animals.

Amorphous or absorbed residues can be very difficult to characterize or identify. These amorphous residues can be formed by degraded trace residues including fat from adipose tissues, dried fluids (e.g., blood, milk, egg), or plant exudates (e.g., resins, gums, oleoresins). Many biomolecules can be found in a residue. The most widely analyzed are fatty acids as these are slightly hydrophobic, well preserved, and can be found in large amounts. Many other categories of biomolecules can also be studied, including hydrocarbons, carbohydrates, proteins, nucleic acids, lipids, resin acids, drugs, alkaloids and hormones.

Residue analysis begins with low-power incident light microscopy, continues with high-powered incident light microscopy, and culminates with the removal of the residue off the surface of the artifact for polarized light microscopy and further analysis. This archaeological microscopy approach to residue analysis is usually capable of identifying microfossils, fibers, scales, particles, pigments, and some traces. Further analysis employing histology, immunology, simple biochemical test, absorbance spectroscopy, Fourier transform infrared (FTIR) spectroscopy, Raman spectroscopy, UV luminescence, gas chromatography mass spectroscopy (GCMS), liquid chromatography mass spectroscopy (LCMS), and elemental, genetic, or protein analysis can characterize and identify archaeological residue even amorphous residues and residual biomolecules. Many of these techniques have been developed for specific residues under specific conditions on a definitive artifact type, for instance, absorbed residues on ceramic (which can appear invisible). Residue analysis can be performed on artifacts made from the following materials: wood, bone, stone, textile, metal, shell, ceramic, glass, antler, horn, and feather. Some key residue types include food, resin, antler, wood, bone, lipids, adhesives, sealants, and blood.

Residue analysis characterizes a residue with sufficient detail to interpret the function or process of a particular tool. This interpretation can include post-excavation contamination, environmental contamination, incidental contact, and non-functionally related transfer. This will allow the archaeologist to define the tasks with which the tool has been associated. Most residue and usewear analysts will begin by first identifying if there is a residue present on an artifact. This is important in order to identify if an artifact has been used. There are two steps – inorganic or organic and anthropogenic or environmental – that follow the confirmation of a residue. These are critical to determine if the residue is the cause of environmental contamination. Determining if the residue is plant or animal, as well as the tissue and taxa of origin, is critical to establish the association of residue and artifact.

Usewear/residue studies of stone, bone, shell, ceramic, and other implements provide key evidence in the history of hunting technology, food processing, resource utilization, and settlement history. Complex hafting of flaked stone tools (whether projectile tips or craft tools) may provide an archaeological indicator of technological sophistication and hence human intelligence, with evident implications for tracking aspects of human evolution (e.g., Lombard and Haidle 2012). Similarly, the history of grinding stone functions may provide an indicator of sophisticated resource utilization and the complex processing of toxic foods and medicines, again with implications for the study of human evolution.

Stone Treatments in Archaeological Conservation and Preservation

Stefan Simon
Rathgen Research Laboratory – National Museums Berlin, Berlin, Germany

Introduction

Since antiquity, treatments of damaged stone have been carried out with the aim to delay the deterioration of buildings and monuments. Today, the

objective of stone conservation is the preservation of these historic and/or artistic values for future generations in the best possible state without compromising the value of authenticity and access. The approach that has been taken to address this challenge has direct links to the emergence of chemistry in the nineteenth century. Chemicals such as water glass, fluorosilicates, linseed oil, and later ethyl silicate were applied as consolidants for stone shortly after their discovery and first synthesis. After World War II, organic compounds, such as acrylic and epoxy resins, were introduced into conservation practice. Nowadays, ethyl silicate and derivatives make up the most prominent group of stone conservation products.

A sound knowledge of the chemical and physical characteristics and of the mechanism through which conservation treatments interact with the stone is the basis for the selection of the most suitable solution for any conservation intervention. However, only rarely are the products available on the market tailored to meet the specific needs of the field of cultural heritage. Moreover, the extremely wide range of porous building materials (both natural and man-made) corresponds to an equally wide range of decay problems and conservation needs which limits the validity of any hurried, superficial appraisal. Therefore specific, cautious evaluation is needed before choosing any product or equipment for each specific case.

There are two main ways to collect the information needed for such careful evaluation: (1) to survey the condition of monuments that have been treated in the past and for which reasonably good documentation exists regarding the methods and materials that were used and (2) to carry out ad hoc tests (either in the laboratory, in situ, or in both contexts, by outdoor exposure programs). Studying the condition of monuments treated in the past is the closest we can get to a real assessment of the performance of products and methods, after a known time interval and under known environmental conditions. The sine qua non condition is, however, the availability of exhaustive, or at least sufficient, documentation of the work that was carried out. The parameters to measure, the measuring methods, and the evaluation criteria have been under continuous discussion in order to improve the evaluation of the long-term performance of treatments through the past decades.

Definition

The primary goal of a stone conservation treatment is to restore in an efficient and durable way the integrity of weathered zones of the object, improve its mechanical and physical properties to the same level as the sound core, while considering the primacy of "retreatability" over the requirement of "reversibility." Stone treatments, whether for consolidation or protection, involve the use of special products for stone conservation.

Key Issues/Current Debates/Future Directions/Examples

The Athens Charter for the Restoration of Historic Monuments (1931) is the first international document which outlines the principles for the conservation of historic monuments. It recommends "... the judicious use of all resources at disposal of modern technique" to delay the decay, while these measures "should be concealed in order not to impair the aesthetic integrity of the monument."

Thirty-three years later, 1964, the Venice Charter calls in article 10: "[...] Where traditional techniques prove inadequate, the consolidation of a monument can be achieved by the use of any modern technique for conservation and construction, the efficacy of which has been shown by scientific data and proved by experience." Article 2 states that "the conservation and restoration of monuments must have recourse to all the sciences and techniques which can contribute to the study and safeguarding of the architectural heritage."

Often, the primacy of reversibility is attributed to the Venice Charter. However, in stone treatment, reversibility remains an only theoretical option. As most treatments, if not all, cannot be considered as reversible, "retreatability" is the desired characteristic of a conservation intervention (Petzet 1993; Giusti 2006), which has been

replacing the concept of reversibility in conservation ethics.

Many papers continued to be published on the results of laboratory tests for stone treatments, both specifically referring to the treatment of specific monuments and to the assessment of a given conservation product or method. Requirements have been specified for different treatments. The research aims assumed that the main objective was not the selection of the "best" product but rather the identification and testing of criteria determined by the stone itself that might lead to that selection (Delgado Rodrigues 1996). Tests for cleaning methods and on the effectiveness of biocides were proposed. The growth in the use of laser cleaning has influenced the experimental studies to evaluate its effects and possible damages.

Since 1985, the Italian NORMAL Committee had dedicated a working group to the problem of evaluating water-repellent products with the specific aim of defining a detailed testing methodology. Evaluation procedures for stone treatments have been discussed at length during the International Colloquium organized by ICCROM in 1995 on "Methods of Evaluating Products for the Conservation of Porous Building Materials in Monuments." The five sessions of the Colloquium were dedicated to the specific problems of testing restoration mortars, biocidal treatments, consolidation treatments, treatments with water repellents, and finally to the important issue of weathering. Each session was followed by a Round Table. A critical evaluation of the papers and of the Round Table discussions was published 1 year later, in 1996, by the experts who chaired the sessions.

H. R. Sasse and R. Snethlage (1997) have proposed a very comprehensive and detailed methodology for the evaluation of stone consolidation treatments based on their own experience and on a previous proposal by D. Honsinger (1990).

Besides the properties to be measured and the related testing methods, Sasse and Snethlage propose to evaluate the results obtained for each parameter making reference to the unweathered stone and to assess them as "% of the optimum." Limits of acceptability are also proposed. According to these authors, penetration depth, hygric dilatation, and E-modulus have the highest priority among the listed properties. The penetration depth must be related to the thickness of the damaged stone or of the zone of maximum mean moisture; hygric dilatation must not increase against the untreated stone, and the E-modulus must not exceed the E-modulus of the unweathered stone by more than 1.5 times.

Accelerated laboratory tests and field-exposure studies, though considered useful and frequently applied, cannot be directly translated into the prediction of the long-term behavior of stone treatments. Nonetheless, many of the difficult points related to field-exposure and to laboratory-accelerated studies are also valid when these conditions are applied to test the durability of treatments. The limited validity of field-exposure tests, as they are constrained by the existing climatic and environmental parameters, and the risk that too high concentration of damage components in accelerated chamber experiments or too high frequency of weathering cycles may lead to results which are far from reality and therefore not useful for the intended purpose are among the main challenges.

For a critical evaluation of the present situation of testing procedures, as they are nowadays commonly carried out, the various steps of the process can be briefly discussed. The aim of the study must be clearly defined in order to select the products (or equipment) to test, the parameters to measure, the type and number of samples, and all the other experimental details.

Once this has been decided, it will be possible to estimate the time needed for the study and its cost. These two points are not insignificant, considering that time and budget constraints frequently limit the possibility to carry out the study, especially when it is aimed at the selection of products for the conservation of a specific monument, within a conservation project where budget and deadlines have already been fixed.

When this is the aim, it is of the utmost importance to refer to the results of preliminary diagnostic studies (characteristics and condition of the stone, main factors of decay, surface typology,

etc.) when planning the experimental details of the testing procedure. To that purpose a strict contact between the laboratory where tests are planned and carried out and the project site is always advisable in order to facilitate the exchange of opinions between conservation scientists and conservator/restorers. This collaboration is especially important when testing cleaning methods. Actually, while their harmfulness could even be evaluated on laboratory samples of the same stone type as the monument, their efficacy has to be tested on the real surfaces, due to the complexity of the various forms of deposits or other dangerous materials to be removed and which are impossible to reproduce artificially.

The last important point of the planning phase concerns the products to test. In the large majority of cases, several products are tested together and compared, as such the results have a relative validity rather than an absolute significance. Whichever the aim and category of the evaluation, the products must be clearly identified (nature and concentration of principal components, solvents, catalysts, additives if any, etc.). Unfortunately, it is not compulsory for producers and retail dealers to declare the detailed composition of products used in conservation; moreover, to characterize these products is not easy for unspecialized laboratories, especially in the case of organic products. It is, however, advisable to reject products that are only vaguely described and to have at least a "fingerprint" of the product to test, such as a FTIR spectrum. This will also help to check afterwards the quality of the product that, having been tested and selected, will be used for a conservation treatment.

When the tests are carried out on stone laboratory samples, they are obtained either from a monument or from the quarry. The first case, however, is not very common, as the amount of samples required for the testing cannot be obtained from a monument, unless some dismantling has to be carried out. In the second case, the quarry stone condition is usually better than the condition of a stone in need of conservation. This may require a preliminary artificial weathering which will, however, introduce an element of uncertainty in the test results.

The problem is even tougher if the tests concern bricks and mortars. If old, damaged samples are not available, as is very frequently the case especially with mortars, it is necessary to produce new samples similar to the damaged ones, and this requires extra work for their production and the subsequent characterization.

Cubes, parallelepipeds, and cylinders are the sample shapes most frequently used; depending upon the different parameters to measure, different shapes may be needed within a single study. The sample size generally ranges from 3 to 7 cm. The more homogeneous the stone, the smaller can be the size. However, when the depth of penetration and bulk properties are considered important in order to assess the efficacy of the treatment, the use of very small samples should be avoided. Working Group 3 within the Technical Committee 346 of the European Committee for Standardization (CEN) is currently preparing further standards for the evaluation of methods and products for conservation works on porous inorganic materials constituting cultural heritage (http://www.cen.eu/).

Nondestructive tests, such as ultrasonic pulse velocity, are given priority over destructive tests, such as for mechanical strength. Parameters that can be measured in profile along the weathered zones are preferred over bulk parameters of the stone as a whole.

Stone, Peter G.

Suzie Thomas
University of Helsinki, Helsinki, Finland

Basic Biographical Information

Peter G. Stone was born in Manchester, UK, in 1957. After school, he first studied at the University of Stirling, gaining both a bachelor's (BA) degree in history and a Diploma of Education (DipEd) in 1979. Over the next few years, he worked as a schoolteacher, teaching history in England, but also teaching English in Greece. In the school summer holidays of 1978 and 1979, and before going to Greece in 1979, he worked as a volunteer at the Coppergate excavations in York with York Archaeological Trust. He was soon drawn even closer to archaeology, completing in 1983 a master's (MA) degree in archaeological method and theory at the University of Southampton. This was followed by a PhD at the same university, supervised by Professor Peter Ucko, with the thesis entitled *Teaching the Past, with Special Reference to Prehistory, in English Primary Education*, combining both his pedagogical experience and his archaeological interests.

Major Accomplishments

Due to working in a number of posts, including as a Project Manager and Coordinator at the University of Southampton for the Archaeology and Education Project set up with Ucko and then in various posts at English Heritage, and with a young family, Peter had the challenging task of carrying out his PhD research on a part-time basis. This achievement both developed in him a wider knowledge and experience of the heritage sector than a full-time student would have gained and also demonstrated his ability to focus on academic research despite many other commitments. It was during his time with English Heritage that he was directly involved

with the infamous controversies surrounding the Summer Solstice at Stonehenge, dealing with this issue in the early to mid-1990s, including while working as Acting Regional Administrator for the South West. His experience with Stonehenge helped establish him as an authority on the site, with numerous publications looking at issues around the site's treatment and management (e.g., Stone 1999, 2006), leading to his appointment in 1997 as the Council for British Archaeology's (CBA's) Special Advisor on Stonehenge (later appointing him CBA representative for Hadrian's Wall, another significant World Heritage Site). The CBA also took advantage of Peter's educational expertise, appointing him Chair of the CBA Education Committee from 1997 to 2003, and he had been a member of the Schools Committee and then the Education Board for the CBA since the mid-1980s.

However, Peter's involvement in heritage reached beyond the UK into international issues from an early stage; he was instrumental, again with Peter Ucko, in driving the formation of the World Archaeological Congress (WAC). From 1998 to 2008, he was the Chief Executive Officer of WAC, and his continued involvement has been credited with providing WAC with administrative continuity and institutional memory (Smith, *pers. comm*. 2011), working from 1986 as head of the unpaid secretariat that enabled the organization to function. During this time too, he was the Executive Series Editor for the One World Archaeology (OWA) Series (1999–2003). He also produced as part of the OWA Series several seminal publications on education and interpretation of archaeological and cultural heritage that are still core textbooks (e.g., Stone and MacKenzie 1990; Stone and Molyneaux 1994; Stone and Planel 1999).

He has also been involved with international heritage management issues for much of his career, for example, through extensive involvement with the United Nations Educational, Scientific and Cultural Organization (UNESCO). For example, in 1996 he was appointed as a member of the Advisory and Drafting Team for the World Heritage Education Project and Kit. His work with UNESCO has also included extensive work overseas. He was personally approached by National Museums and Monuments of Zimbabwe (NMMZ) to carry out a review of their education service, compile a report on its future development, and then implement some of that development – in particular a 7-week training program for education and interpretation staff in NMMZ. In addition, sabbatical visits to Australia and New Zealand as visiting lecturer at Flinders and Auckland Universities in 2004 and work in China in 2008 with the International Centre for Chinese Heritage and Archaeology (ICCHA) reinforce the regard in which his expertise is held internationally.

In 1997 Peter joined Newcastle University as a lecturer in heritage studies at the Department of Archaeology. He developed the popular MA program in Heritage Education and Interpretation and was the Director of the International Centre for Cultural and Heritage Studies at Newcastle University from its formation in 2001–2005. Following this, he moved to becoming Head of School of Arts and Cultures at Newcastle University, also becoming a Professor in 2005. In 2016 he became UNESCO Chair in Cultural Property Protection and Peace at Newcastle University.

From a research perspective, Peter has recently been involved with exploring the controversial issues around heritage management during armed conflict, stemming from his appointment in 2003 as advisor to the Ministry of Defence with regard to safeguarding the archaeological heritage in Iraq in light of the impending conflict. As well as an award-winning publication coedited with Stone and Bajjaly (2008) and the development of a touring exhibition in partnership with the Oriental Institute in Chicago exploring the impact of the destruction of cultural heritage in Iraq, this experience has also led to Peter's continued lobbying of the UK government to ratify the Convention for the Protection of Cultural Property in the Event of Armed Conflict with Regulations for the Execution of the Convention 1954. Related to this, he is also the Chair of the UK Committee of the Blue Shield. Peter also continues to

be interested in other heritage management issues, chairing the Hadrian's Wall World Heritage Site Management Plan Committee and sitting on the National Trust's Archaeology Advisory Panel.

Peter Stone's career has been highlighted with much esteem for his influential and groundbreaking contribution to international heritage studies. In 2011 he was awarded the Order of the British Empire (OBE) in the Queen's Birthday Honours list for services to heritage education. In 2013 Peter was awarded the Peter Ucko Memorial Award and a Lifetime Achievement Award by the World Archaeological Congress – both for services to world archaeology. Peter currently lives in Northumberland with his wife and four children.

Introduction and Definitions

Stone represents a hard substance typically composed of mineral and/or rock matter, which is quarried, or simply found, and worked into a specific form and size for a particular purpose such as construction, paving, and adornment, or as powders (e.g., pigments). Stone is exceedingly varied in its distribution, characteristics, and application; however before its broad diversity can be discussed, important definitions must first be addressed.

***Mineral*:** a class of naturally occurring substances comprised of inorganic compounds (carbonate) and elements (carbon) that exhibit a specific chemical composition, crystal structure, and optical characteristic. Specific minerals may include diamond, feldspar, quartz, and talc. ***Rock*:** substance comprised of varied minerals either as individual mineral materials (e.g., graphite) or variable minerals constituents (e.g., granite). Rock can be created in nature through heat and/or pressure (marble) or through the actions of water and time (e.g., limestone). Rocks are basically composed of one massive mineral, or simply a mosaic of many. ***Weathering*:** rock surface deterioration caused by various mechanical and chemical processes through in situ influences. Causes are grouped as intrinsic and include characteristics of rock type, permeability, and surface texture, while extrinsic agents represent external or noninherent factors such as sunlight and rainfall. ***Erosion*:** rock surface deterioration and weathering specifically due to the moving action of water and/or wind (e.g., waves, rainfall).

To understand stone use and treatment, it is crucial to understand their classifications that are based upon their primary environments of formation: heat, water, and pressure. Rocks are divided into three rock types of igneous (primarily fire), sedimentary (primarily through secondary deposition), and metamorphic (primarily through heat and/or pressure alteration).

Igneous Rock

These rock materials are often the least likely to deteriorate quickly in art, archaeological, and architectural settings. They typically develop in high-temperature environments (crust, mantle) and are divided into two basic groups: intrusive and extrusive. These rocks are classified based on their formation and composition. ***Intrusive rocks*** and minerals include those materials that are formed in high temperature settings deep within the Earth, or near the Earth's surface (e.g., volcanoes). In general, those rocks forming deep below the surface develop coarse particle sizes (like diamonds and granite), while those forming near the surface have smaller particles. Intrusive stones include granite, gabbro, and porphyry. For example, the stone blocks of Machu Picchu (Peru) were cut from granite, while Pyramids of Giza (Egypt) were originally faced in red granite from Aswan. However, the granite sheets were robbed over the years to leave the limestone core blocks remaining. The monumental columns of the Pantheon in Rome (Italy) were hewn from granite, while its interior's large circular floor panels were composed of a rare, blood-red porphyry. ***Extrusive (or volcanic) rocks*** form near or on the Earth's surface and have a fine-grain size often as "lava" materials including rhyolite (light colored), andesite (gray, brown), or basalt (dark colored). Volcanic rock may be ejected as well (supercooled) to form igneous glasses like obsidian or scorious (with cavities) materials like pumice. For example, rhyolite (tuff) was used for the popular "peperino" building material in Rome (Italy) and the mo'ai statues of Easter Island (Rapa Nui).

Although all extrusive and intrusive rock materials are found in construction or as artifacts, their overall hardness makes them often difficult to work as structural masonry. However their hardness also makes them resistant to scratching and ideal in adornment and as small tools.

Sedimentary Rock

These rock materials include some of the most widely used rocks in construction and conservation and include limestone and sandstone. Although most of the Earth's crust is composed of igneous rock, most of it is covered by a thin veneer of sediments and sedimentary rock. These rocks are formed as layers of our crustal sediments become compacted, cemented, and hardened (indurated, lithified). Sedimentary rocks are considered secondary, because they are formed as the result of the accumulation of smaller portions of pre-existing rock materials like other sedimentary or igneous and metamorphic rocks. There are three categories of sedimentary rocks that are based upon the type of particle from which it developed. ***Clastic*** sedimentary rocks are comprised of accumulations of small pieces of broken-up rock (or clasts) that have accumulated and lithified over time through compaction and/or cementation. For example, accumulated and cemented beach sand develops into sandstone over time. ***Chemical*** sedimentary rocks develop when chemically rich water evaporates, leaving floating or dissolved minerals to concentrate. Chemical-type rocks are most prevalent in arid environments where seasonal or ephemeral ponds (playa lakes) develop in closed depressions. For example, salt and gypsum deposits form from repeated flooding and evaporation over long periods. ***Organic*** sedimentary rocks represent the accumulation of organic debris such as large shells (cochina), fine shell material (chalk), and plant material (coal).

Sedimentary rock materials represent one of the most widely used building materials and include the limestone blocks of the Pyramids at Giza (Egypt), the carved sandstone Buddha of Leshan (China), and the architecture of Petra (Jordan), the travertine of Saint Peter's Colonnade (Italy), and the elaborately carved salt mine architecture of Wieliczka (Poland).

Metamorphic Rock

From "meta" (change) and "morph" (form), any rock can develop into metamorphic rock through a

change in heat and/or pressure. Over time, with increased pressure limestone becomes marble, the most popular sculptural and statuary material, and mudstone and shale alter into slate. This change may involve the rock moving into a different environment, or the environment changing around the rock material. These re-cooked and restressed rocks include marble, slate, gneiss, and schist. For example, the Taj Mahal in Agra (India), Il Vittoriale in Rome (Italy), and the US Supreme Court Building (USA) are all constructed of white marble. Other metamorphic building materials are much less common; however schist, phyllite, and gneiss are used in stone architecture. We must be reminded as well that many rock materials do not confirm to one classification, since the transformation processes may be localized or incomplete. Hence, limestone may have marbleized portions, or granites may have gneissic margins.

Weathering and Deterioration

Since stone materials are so varied in composition, texture, density, and integrity, their rates of weathering, influences on weathering, deterioration features, and change in integrity over time are as diverse. So to address stone preservation, one must first examine the broad factors involved in stone deterioration as well.

Weathering is the breakdown of rocks (and minerals, soils, metals, glass, etc.) through the interaction with the atmosphere, climate, biota, and anthropogenic factors (e.g., pollution). The processes of weathering occur in situ and are not to be confused with erosion, which involves deterioration and degradation by influences that involve movement including moving water, wind, ice, and gravity. Weathering is conventionally classified into (a) physical and (b) chemical weathering. **Physical** (or mechanical) weathering involves the breakdown or disintegration of stone through direct contact with climatic influences, whereby the weathering by-product is the same as the pre-weathered material. Physical weathering causes the disintegration of rocks without chemical change. For example, freezing water can expand surface cracks in rocks that cause the material to breakdown and off. **Chemical** weathering however involves the breakdown of rock surfaces through chemical reactions influenced directly by the atmosphere, biota, and climate. It is a gradual process as the mineralogy of the stone adjusts to the surface environment, and/or to the contact changes (wind, water, humans). New or secondary minerals can develop from the original rock minerals – the processes of oxidation and hydrolysis being the most prevalent. For example, acid rain eroding the surface of a marble statue produces a by-product unlike the pre-weathered rock.

Chemical and physical weathering, however, most often work in tandem. One process is rarely the only weathering agent, but instead the two influences work together to breakdown rock material. For example, cracks expanded by physical frost action (cryo-fracturing) will increase the surface area of the weathering rock, exposing more material to chemical reactions and further breakdown. Biologic weathering is a term used for the influence of plants and animals on rock breakdown. Plants and animals may create chemical weathering through release of acidic compounds. For example, lichen overgrowth on rock produces fine roots (rhizines) that physically attach, penetrate, and disaggregate the rock substrate, while oxalic acids released from the lichen roots can chemically deteriorate the substrate as well (Paradise 1997).

Many of Earth's landforms, surface features, and landscapes are the result of weathering processes, in conjunction with erosional forces. In the fields of material conservation/preservation, and heritage management, it is imperative that an identification and understanding of weathering and erosional characteristics is addressed before assessment and treatment may be undertaken. Questions as to why sandstone weathers differently than limestone or granite, for example, are crucial in stone conservation and preservation. Hence, a discussion of the diverse weathering influences on the assorted stone materials follows.

Physical weathering phenomena include a number of influences that can degrade the surface of stone and ultimately lead to decreasing the integrity of the structure as well. *Disaggregation and*

spalling: in rock materials made up of particles (cochina), minerals (granite), or clasts bound by matrix (sandstone), weathering agents can cause decay through disaggregation. With repeated heating-cooling (thermal stress), and freezing-thawing, the aggregate may loosen from the rock material, and fall away, causing surface recession. The expansion of freezing water ($\leq$10%) may be enough to pry a particle from its substrate. Also, the expansion of a heated surface particle, crystal, or clast may also cause its disaggregation. Disaggregation can be common in environments where temperature ranges are greatest, like deserts. Similarly salt heaving occurs when salts within or adjacent to the weathering material can migrate (when soluble) into the surface particles to evaporate, crystallize, and expand, causing salt heaving and disaggregation as well. Hydration occurs when rock and minerals expand upon saturation and are pried from the substrate and deterioration as well; this can be a process that involves both physical and chemical weathering processes as well. When rock minerals take up water, the increased volume creates physical stresses within the rock and act again to pry apart particles, crystals, and rock materials.

Since some rock materials (e.g., sandstone, granite) formed deep below the Earth's surface, when erosion and/or uplift exposes them, this removal of overburden represents a huge decrease in material pressure. Hence, the material will expand causing small (micron) to moderate (centimeter) fractures to develop. This "unloading" can cause large-scale surface deterioration and structural damage through sheeting, peeling, and spalling (Smith and Warke 1996).

Chemical weathering influences include a number of influences that can deteriorate the surface of stone, leading to overall deterioration, surface recession, and damage as well. *Dissolution and hydrolysis* is the weathering process whereby acidic solutions (e.g., acid rain, groundwater) degrade rock material through the acidic breakdown of some rocks (e.g., limestone, marble) and minerals. In many cases, hydration is also a chemical process, for example iron, when iron oxides change to iron hydroxides and the hydration of anhydrite forms gypsum. Hydrolysis commonly affects silicate (e.g., arenite) and carbonate minerals in rock (e.g., limestone). For example, water can ionize/acidify to react with silicate minerals resulting in the dissolution of the original mineral. *Oxidation* typically involves the transformation of metals and metallic components. In stone, most process involves the oxidation of iron or copper through the combination of water and oxygen. This change to iron or copper oxides produces a rust-like stain in iron from the development of new minerals like hematite and limonite, or a green stain (verdigris) in copper with the transformation into new minerals like chalcopyrite. This rusting or verdigris decreases the overall rock integrity and hardness.

Conservation Applications and Treatments

Contemporary conservation efforts now often examine and monitor deterioration influences and conservation at four different scales: (a) molecular material scales (e.g., microscopic examinations, submillimeter), (b) surface material scales (e.g., rock surface detail, millimeter-centimeter), (c) structural levels (e.g., for partial restoration of a temple, centimeter-meter), and at (d) the broadest urban/regional scales (e.g., classical period city reconstruction, meter-kilometer). All examination, conservation, and monitoring levels must address both extrinsic (i.e., climate, humans) and intrinsic (i.e., stone composition, integrity) influences on stone deterioration, so the techniques used in their conservation must affect these factors directly. Conservation procedures can then (i) reduce material susceptibility to weathering and erosion forces and/or (ii) increase its resistance to them. At many sensitive sites like Petra (Jordan), or Machu Picchu (Peru), extrinsic deterioration factors such as human touching, climbing, and treading, may be diminished simply through enforced policies that either prohibit or require certain aspects of behavior, banning entrance, prohibiting climbing, or simply climbing over, on, or near sensitive materials and sites. These simple policies have proved effective in

Stone: Preservation and Conservation, Fig. 1 Erosional rillen from rainwater-entrained sand, Petra, Jordan. Rushing water from torrential rainfall entrains and mobilizes sandgrains from the sandstone, which then in turn further abrade the substrate sandstone producing these channels (or karren, rillen). The sandstone substrate was hewn by the Nabataeans approximately 2000 years ago

Stone: Preservation and Conservation, Fig. 2 Tafoni (stonelace, alveoli) in Petra, Jordan. Complex feedback cycles of wetting and drying, hardening, and disaggregation are responsible for this characteristic cavity development. This alveolar weathering is observed here on a surface dressed 2000 years ago, so the surface recession from weathering may be determined at 1–2 cm/millennia

Stone: Preservation and Conservation, Fig. 3 Natural limestone decay in Malhamshire, UK. The pavement-like appearance is due to the deterioration of the surface limestone through dissolution and its acceleration from rock fractures and natural cavities in these karst landscapes

decreasing deterioration including human-induced abrasion, and humidity shifts (from respiration, perspiration, and transpiration). Such restrictions may act not only to decrease overall stone weathering and erosion but to also create a sense of patrimony and caring among visitors to these sites. Understanding that all people are a part of our Earth's patrimony, protection, and salvation may in fact instill a sense of legacy and heritage – a more pervasive conservation concept.

In addition to policies related to restricting or facilitating behavior, the first step in effective stone conservation and material/structural maintenance involves the removal of salts (efflorescence), plants, and lichens from the surface, whereby their removal, in many cases, can decrease the rate of erosion and weathering. New applications are now being tested (e.g., "cocoons") where a

Stone: Preservation and Conservation, Fig. 4 Comparative sandstone capitals hewn from the Pietra Serena Sandstone in the Ospedale degli Innocenti, Florence, Italy, designed by Filippo Brunelleschi (15th C). The disparity in weathering in the sandstone architecture can be attributed to variations in insolation, thermal stress, and environmental fluctuation

Stone: Preservation and Conservation, Fig. 5 Lichen-induced weathering/spalling of sandstone, Lamlash Church, Arran Isle, Scotland. Lichen attachment and rhizine penetration of the red sandstone substrate is accelerating the spalling and disaggregation of the architectural stone. Lichen overgrowth can temporarily facilitate surface induration and then subsequently cause large sheet spalling

Stone: Preservation and Conservation, Fig. 6 Travertine (tivoli limestone) deterioration is evident across Bernini's Colonnade at St. Peter's Basilica, Vatican City, as observed in the uneven pitting and surface recession of the column drum. Accelerated weathering of the travertine has been attributed to a number of factors including biotic (cyanobacteria, moss, lichen) overgrowth and penetration, biogenic acid production, urban-generated acid rain, and environmental agents (e.g., thermal stress, wetting-drying)

thick poultice is applied to the stone surface to absorb salts and particulates, so that upon their removal, surface pollutants and salts are removed as well. However, early tests have indicated that some of the stone substrate is also removed – a dangerous and detrimental circumstance in stone conservation practices, however the technique shows great promise.

Once the deteriorating materials have been appropriately cleaned, the use of surface consolidants is increasingly conventional in strengthening stone integrity and fabric. Conservation methods and application are meant to address the influences of intrinsic weaknesses that can accelerate rock weathering and erosion. Over the millennia, on rock and mineral structures, artwork, and monuments, liquids and waxes have been applied in the hopes that disaggregation can be controlled through the

better adherence of the components of the stone materials. Vitruvius (15 BC) described the use of beeswax as a means of consolidating and waterproofing stone, and similar applications have been tried since. These organic applications are increasingly rare; however inorganic washes such as calcium carbonate plaster and slurry were also widely used then and now. In fact, in sensitive stone materials like Petra's sandstones, plaster applications (for consolidation and/or fresco overlay) were widely applied and are still visible today on chamber walls, façades, couloirs, and staircases, where the carbonate coating has been protected from the destructive influences of sunlight, extreme temperature cycles, touching, precipitation, and woodfire sooting (Paradise 2011).

Contemporary stone surface and near-surface consolidants are categorized as synthetic (organic) polymers, silanes (alkoxy), epoxies, and waxes. Early experimental trials from the 1970s utilizing polymer consolidants (i.e., Paraloid©) are still often evident on limestone and sandstone applications across Asia, Europe, and the Mediterranean (Wheeler et al. 1984). Organic resins are typically irretrievable, and over time they tend to discolor, bleach, and peel (Paradise 2015).

Silane applications have been used since the 1980s (e.g., Wacker OH©) and are organosilicon compounds that permeate the voids in stone (e.g., sandstone) strengthening its mineral fabric, and decreasing its overall permeability (and active porosity) by creating a silica gel that fills the voids, binds the clasts, and "waterproofs" the stone. Silane applications have proven to be effective consolidating agents when the whole object may be immersed, so that the solutions may penetrate all portions of the sandstone in question, such as a statue. However, when applied to stone such as sandstone in situ, like the façade of a monument, variability in penetration depths and coverage permits moisture to become trapped or enter and mobilize behind the silica skins. Once this occurs, rather than the normal disaggregation of the clast from the rock, spalling and sheet collapse can occur. The results of silane use in conservation will either represent an exemplary warning against future use, or an excellent model for continued applications on important deteriorating stone architecture (Paradise 2011).

Overall, the field of rock weathering and stone conservation is relatively new, and theoretical research and applied innovation will continue to help us to more effectively and efficiently protect our stone cultural heritage. Since our architectural and archaeological rock and mineral materials are so diverse, treatments and applications used to decrease their weathering and deterioration must also be as varied. So as research and technology grows and develops, our ability to preserve our precious past will grow, and our stone heritage will remain for us to experience and cherish longer and longer.

Strategic Environmental Archaeology Database (SEAD)

Philip I. Buckland[1], Mattias Sjölander[1] and Erik J. Eriksson[2]
[1]Environmental Archaeology Lab., Department of Historical, Philosophical and Religious Studies, Umeå University, Umeå, Sweden
[2]ICT Services and System Development (ITS), Umeå University, Umeå, Sweden

Introduction

Environmental archaeology encompasses a wide range of scientific methods for analyzing the results of past human activities, environments, climates, and perhaps, most importantly, the relationships between these. Many of these methods are referred to as *proxy analyses*, denoting the illumination of the past as interpreted indirectly through the evidence of fossil organisms or properties. These lines of evidence, or proxy data sources, are assumed to reflect past conditions by way of their dependence on them. For example, a species of beetle may only survive within a specific climate range, and thus its presence in samples indicates this climate at the time of deposition; organic waste deposited around a farmstead will raise soil phosphate levels above those of the surrounding land; and the presence of cereal grains in postholes suggests their local cultivation or import, usage, or storage. While it is easier to store, manage, and analyze the data produced by these methods individually, there is much to be gained from multi-proxy integration at the raw data level, especially with respect to providing a framework for a more holistic interpretation of evidence.

Despite the considerable methodological diversity in environmental archaeology, the common factors of space, time, and sampling/archaeological context should allow us to cross-correlate and integrate the results of analyses. This is, however, easier said than done, and without efficient data handling, the data rapidly become unmanageable. SEAD (n.d.) represents one solution to this problem, and forms a node in an international web of open-access paleoenvironmental and archaeological databases which are driving archaeological science into new realms of more complex, multi-site, multi-proxy analyses and meta-analyses. This entry sets out to describe the system, the scientific goals of which were set out in Buckland et al. (2010) and Buckland (2013).

Definition

The Strategic Environmental Archaeology Database (SEAD, http://www.sead.se) is a research data infrastructure for the storage, management, analysis, and dissemination of environmental archaeology and Quaternary science data. The database covers a large number of proxy data sources, ranging from insects and dendrochronology to ceramic thin sections and ^{14}C dating (Table 1). It is an open-access project, initially financed by the Swedish Research Council and Umeå University, Sweden, with subprojects funded by Lund University. Further development has been financed through The Swedish Foundation for Humanities and Social Sciences VISEAD infrastructure project (www.visead.se), and additional funds from Umeå University. The system provides unrestricted access to raw data from archaeological and Quaternary science investigations, and has technically no geographical or chronological limits. Although its scope is international, SEAD is registered as a national research infrastructure at the Swedish National Data Service (SND 2017). SEAD is multidisciplinary in nature, and the project aims to encourage, support, and empower research that transgresses traditional disciplinary boundaries, just as the data do.

SEAD is interfaced either by a downloadable software package (which will be eventually replaced by an online system) for data management and offline use, or an online faceted browser system for data retrieval only ("QSEAD", http://qsead.sead.se, Fig. 2). Analysis tools are planned in collaboration with partner systems (see section

Strategic Environmental Archaeology Database (SEAD), Table 1 Scope of the proxy data currently stored in SEAD as well as potential for expansion and limits. At the time of writing, SEAD contains approximately 2000 sites from 4 data sources (Table 2; Fig. 1), each of which is continually being updated

Proxy data sources	
Biological proxies	*Current:* Fossil occurrences of insects/arthropods, plant macrofossils, pollen
	Future: Any organism or pseudotaxon can be added to the taxonomic list. Osteological material may be better catered for in other systems (e.g., Neotoma 2009), but North Atlantic animal bone data is being entered
Geoarchaeology	*Current:* Soil chemistry (pH, phosphates) and physical properties (conductivity, magnetic susceptibility, organic content, color)
	Future: Any quantified or qualified chemical or physical property can be stored
Ceramics	*Current:* Thin section quantification and properties (clay content, tempering, grain size, firing temp., firing atmosphere, melting point)
	Future: XRF and (summarized?) multispectral data
Dendrochronology	*Current:* Ages, supporting analysis data, historical building metadata, sampling location
Organic biomarkers	*Planned:* Through the Archaeological Research Lab, Stockholm (AFL), and the VISEAD project (www.visead.se)
Compound-specific stable isotopes	*Planned:* Through the Archaeological Research Lab, Stockholm (AFL), and the VISEAD project (www.visead.se)
Methods	Detailed descriptions and references are stored for all methods (e.g., preparation methods, dating methods, analysis methods), and method variations are stored as separate methods. Sample pretreatments may be stored parallel to analysis and sampling methods
Dating evidence	
Scope	*Current:* ^{14}C and other radiometric methods, dendrochronology, archaeological typological dates, period classifications, calendar dates, and ranges
	Future: Any method and period systems compatible with the current structure
Chronological extent	Theoretically unlimited, but current data range from 2.4 MyBP to present day
Bibliographic data	
References	May be linked to site, sample group, sample, and dataset levels as well as to methods, ecological codes, and more
Modern reference data	
Abstracted text	*Current:* Insect habitats and distributions, abstracted from trusted sources, with citations
	Future: Any amount of abstracted text-citation couplets may be entered for a taxon (taxa are currently biological organisms, but this is not necessarily restricted)
Coded descriptors, classifications, or species traits	*Current:* Insect ecology (traits/classifications and abstracted texts – see "Paleoentomology" in cross-references), plant functional types/traits, and archeo-/ethnobotanical classifications
	Future: Any taxon may be classified according to any number of user-defined coding systems
Climate	*Current:* Beetle species thermal envelopes – Mutual Climatic Range (MCR) temperature reference data (see "Paleoentomology" in cross-references)
	Future: MCR, or potentially other types of climate reference data, for more insect species and plants
Locational data	
Coordinates	Three dimensional at site, sample group, and sample levels (latitude, longitude, altitude, and project survey grids)
Geographical extent	Mainly European, but potentially global

(continued)

S

Strategic Environmental Archaeology Database (SEAD), Table 1 (continued)

Archaeological data	
	Current: Site, feature, and sample metadata to allow correlation between environmental and archaeological or lithology datasets. Any number of features can be added, and they may be given multiple names (e.g., field label, lab number, museum number). Descriptive information may also be added for structures and ceramics as required
	Exceptions: Coordinates can be stored for samples or groups of samples, but not features or contexts
	Future: True geospatial/geographical object storage

Strategic Environmental Archaeology Database (SEAD), Fig. 1 Geographical location of sites stored in SEAD (as of 24 August 2017), categorized by data source (see Table 2 for clarification). Black triangles indicate sites in the dataset against a backdrop of white circles showing all sites in SEAD. Note that individual MAL sites generally include several proxies and Dendro and Ceramics lab sites include multiple variables

"Future Directions"), but at the moment users may download query results from the browser and undertake further analyses in other software. The browser facilitates research that goes beyond the scope of the projects which have contributed data in that, while maintaining full traceability in terms of source publications and authors, it searches in ignorance of the origin or purpose of the datasets. For example, a user may ask for all incidences of a species (e.g., the grain weevil, *Sitophilus*

Strategic Environmental Archaeology Database (SEAD), Fig. 2 The SEAD online faceted browser and data map, QSEAD. Available filters (facets) are labeled across the top of the window. Clicking on a label makes the filter available on the left, showing the available content for (multi-)selection. In this example four filters have been activated: Country (Sweden), Proxy type (Plants and pollen), Genus (several cereal genera), and Abundances. The first three have been used to reduce the data, and thus limit the display of points on the map, to the occurrence of cereal grains in Sweden. The Abundances facet shows the frequency of these finds in samples, but can also be used to restrict the results to a range of numbers (e.g., >10 seeds). The pattern of points in the map suggests that, in Sweden, these fossils are most often found during excavations connected to infrastructure (road or railway) projects

granarius, Fig. 3), and retrieve data from multiple investigations, be they research or consultancy excavations, or Quaternary geological investigations. They may then, in the same interface, narrow their search geographically or chronologically, expand it by adding other taxa (animals or plants) or soil properties, or just export the data, which is fully referenced. An alternative approach, which is possible in the same browser and may or may not produce the same results, would be to filter by ecological traits to reduce the initial scope of inquiry to only "Stored grain pests," retrieving information on the past distribution several species which have similar habitat traits to the grain weevil. The system can thus be used to investigate similar data from the perspectives of both paleobiogeography and cultural history (more discussion on this particular example can be found in Panagiotakopulu and Buckland 2017, where the BugsCEP dataset is used to help in a wider synthesis of pest dispersal).

The classification of plant and animal species according to their traits or habitat preferences, or with reference to ethnographic records (Table 1), and the provision of facetted browsing, allows the same online interface to be used for the interrogation of the data from multiple angles. This capacity to reverse the point of inquiry increases opportunities for the classic "outside the box" thinking, and may stimulate new and interesting

Strategic Environmental Archaeology Database (SEAD), Fig. 3 Four maps showing the archaeological data in SEAD (extracted 24 August 2017) for the spread of the (flightless) grain weevil, *Sitophilus granarius*, from its probable origins in the Eastern Mediterranean. The figure serves as an illustration of both the power of the database for understanding the relationships between cultures and animals, and the importance of understanding the nature and quality of the data before drawing conclusions. (**a**) Shows the oldest date (BP) for each site, with triangles indicating calendar dates (e.g., dendrochronological or coin based), white circles indicating broad period limits (e.g., start of medieval period), and black circles the older two standard deviation limits of calibrated radiocarbon dates. Note that the inclusion of broad and geographically vague periods (e.g., medieval) where no secure dating is available leads to the appearance of either too old or too young dates – the apparent appearance of the beetle in Iceland *before* it was colonized in the ninth century is clearly incorrect. Chronological periods need to be assigned with care over their geographical relevance if there is a risk of the data being used out of context, and there is an apparent need for updating the database here. (**b**) Shows an inverse distance weighted interpolation of the dates, with darker areas representing older dates, and where the frequency/density of sites is at least partially confounding the known story of dispersal with crop storage which is expressed in (**c**) (see Panagiotakapulu and Buckland 2017 for more discussion of the spread of insect pests). (**d**) Shows the 262 GBIF (Global Biodiversity Information Facility, www.gbif.org, accessed 24 August 2017) occurrence records for *Sitophilus granarius* L. (https://doi.org/10.15468/dl.b1vqs6) and *Sitophilus granarius* Gyllenhal (https://doi.org/10.15468/dl.dgzndm) (see text). Although modern pesticides have undoubtedly reduced the prevalence of the species, in the light of the historical data, it is doubtful that this represents its true modern distribution. "*Sitophilus granarius* Gyllenhal" is also an incorrect designation for the species which could cause problems for automated data harvesting systems, or users unfamiliar with the species

insights (such as looking for a reduction in the prevalence of multiple proxy indicators for trees, then looking in other databases for the co-occurrence of agricultural artefacts). The ecology angle is potentially very powerful, in that it allows rapid visualization of sites where specific environments/habitats/species traits are represented from multiple sites, and may thus provide data for more advanced GIS analyses (see, e.g., Buckland 2017). The power of this system derives partly from a flexible query engine, designed at HUMlab in Umeå, and partly from a highly normalized relational database structure which allows intuitive cross-querying between the smallest divisible, structured data entities.

Historical Background and Related Systems

The development of SEAD was initiated at the Environmental Archaeology Lab (MAL) and implemented in collaboration with the Humanities Computing Lab (HUMlab), at Umeå University, in 2008. The database design and user requirements were outlined primarily in discussions with MAL's research network partners and benefitted considerably from close communication with the ongoing BugsCEP (Buckland and Buckland 2006) and Neotoma (2009) projects. Discussions and skill sharing between these projects have ensured compatibility between the databases and will help to ensure the efficient use of public funds by negating the inevitable reinventing of the wheel when similar projects run independently (albeit directed at different user groups). A dialogue has also been maintained with a number of local and regional database projects and archive centers, especially the UK's ADS (n.d.; Archaeological Data Service, http://archaeologydataservice.ac.uk/) and the Swedish SND (Swedish National Data Service, https://snd.gu.se/en), as well as the international archaeological and Quaternary science community at large.

The Swedish National Archaeological Resource labs for dendrochronology (VDL) and ceramic research (KFL), in Lund (Table 2), joined the project in 2011 and expanded the scope beyond the original design. After some database redesign, this enabled the entry of large amounts of thin section ceramics data (see below), and initial test datasets of dendrochronological data from archaeological and building heritage management sites. The Archaeological Research Laboratory (AFL) in Stockholm joined SEAD in 2016 through the VISEAD project. These laboratories are members of the incipient Consortium of Swedish Archaeological Research Laboratories (ArchLab, http://www.archlab.se), for which SEAD will be the research data infrastructure.

SEAD's focus is on environmental archaeology data in its broadest definition, including the ecological and archaeological reference data which are necessary for its interpretation. Where the latter are outside of the scope of SEAD (e.g., detailed

Strategic Environmental Archaeology Database (SEAD), Table 2 Initial data sources ingested into SEAD originate from the partners in the Consortium of Swedish Archaeological Research Laboratories (http://archlab.se/), and the BugsCEP database. Sites currently digitized (although not all are available online) and with locational data are shown in Fig. 1, with the letters A–D in this table corresponding to the letters on Fig. 1

S

excavation data, modern species distributions point data), it must provide sufficient metadata for a user or automated system to form the appropriate links or extract data. In this respect, all archaeological and biological databases or repositories could be seen as related systems, and the SEAD team engages in continual dialogue with a number of these. At the time of writing, there are still few databases available with a similar multi-proxy, multi-site scope to SEAD (a fact which most likely reflects the difficulty in acquiring the considerable amount of funding required). Neotoma (2009) is perhaps the closest system, the primary differences being that the latter is more orientated toward Quaternary geology than archaeology, and does not currently aim to store modern reference data to the same extent as SEAD. However, Neotoma can technically store coded habitat data or traits, and it thus has a potentially similar functionality to SEAD's habitat summarizing capacity. Neotoma is also able to plot pollen diagrams and age-depth curves online, something which SEAD is not yet capable of doing, and there are clear opportunities for collaboration and tool sharing. The transfer of data is enabled through Neotoma's well-developed API (Goring et al. 2015) and the equivalent in SEAD, and there are plans for mirroring a subset of SEAD's data in Neotoma. The US-based Digital Archaeological Record (tDAR 2017) also overlaps the scope of SEAD to an extent, providing an excellent and well-supported infrastructure for archaeological data with the facility for storing environmental archaeology results. tDAR is perhaps, at least at the moment, more orientated toward project/site archiving than site-independent and inter-site analyses than SEAD. Both Neotoma and tDAR feature advanced interfaces for data management and data interrogation, but currently without the flexibility of faceted browsing.

Relating Archaeological and Environmental Data

An essential capacity of an environmental archaeology database is the ability to store metadata which will allow users to relate sample data and analysis results to the archaeological features from which they are derived. SEAD is not an excavation database, and stores only enough information as necessary to locate a sample in an archaeological plan, report, or another database. These data are frequently missing in both the scientific and gray literature, and may often have to be collated from other archive sources (such as county records, original lab reports). While excavation databases commonly allow the logging of sample names, locations, and purposes (e.g., macrofossil sample, ^{14}C sample), they are generally not designed to hold the results of any analyses. Similarly, archaeological sites and monuments records (e.g., the Swedish FMIS, 2017), archiving systems (e.g., the UK's ADS, 2017), and inter-archiving portals (e.g., Europeana, n.d.) do not as yet explicitly store sample metadata, environmental data, or results in a cross-queryable form. However, some systems, such as ADS, do store or link to a number of reports which do hold these data, and there is potential for more interaction between these systems. As well as catering for multiple alternative sample names (e.g., field number, museum number, lab reference), SEAD provides multiple levels of metadata storage for archaeological features, contexts, and objects. Due to the multi-subject scope of the system, this has had to be flexibly implemented with sets of tables for free text descriptions which are defined by selection from list of predefined types (to which advanced users can add). This also allows for some level of interpreted data into the sample and sample group metadata, setting the context for the environmental data independently of external sources (Table 3). It also makes the development of simple user interfaces problematic.

Taxonomies

A problem for international databases containing biodiversity data is the maintaining of consistency of taxonomic records and providing lists of species in taxonomic, rather than alphabetical, order when required. SEAD's approach is to provide a taxonomic master list which allows the entry of any taxon, providing it is approved by the clearing house (see below), as well as synonyms and multiple taxonomic ordering systems. This allows, for

Strategic Environmental Archaeology Database (SEAD), Table 3 Samples and groups of samples can be assigned descriptive metadata of specific types, to help relate them to excavation (field or report) or antiquarian objects. This capacity also provides key data for inter-archive linking. Multiple samples can come from the same feature, and in some cases, where the stratigraphy is complex or has been revised, a sample can come from multiple features

Data context	Field	Example data
Archaeological	Feature type	Hearth
	Feature type description	Feature with evidence of burning, the base of a fireplace, probably used for cooking, heating, or metallurgy
	Feature name	H1
	Feature description	Sami hearth at top of ridge
Dendrochronological: building antiquities	Object description type	Building category
	Object description	Secular
	Object description type	Building category
	Object description	Residential building
	Object description type	Building function
	Object description	Mangårdsbyggnad
	Object description type	Building function
	Object description	Two-floor
Ceramic	Object description type	Vessel
	Object description	Trattbägare (funnel-neck beaker)
	Sample description type	Vessel part
	Sample description	Mynning (rim)
	Sample description type	Surface treatment
	Sample description	Grafitbelagt kärl (graphite coated)
	Sample description type	Decoration
	Sample description	Grafit (graphite)

example, a species which is present in both the British and North American beetle catalogues to be stored, with the lists having their own exclusive content. Two species which are unequivocally matched can be related to each other in a separate taxonomic list, thus allowing for cross-correlation, but preserving the original separation for the sake of transparency. If data are entered using a taxonomic list which has water beetles after ground beetles, rather than before (which is important for some entomologists), then separate taxonomic coding systems can be implemented to provide for the differences. In such an event, the difficult task is defining the coding system rather than making it fit into the database.

Open Access and Datasets

SEAD is committed to open access and transparency, with all datasets being uniquely identified so that updates can be traced, with unique dataset DOIs (Data Object Identifiers) acquired through the Swedish National Data Service (SND). Modified datasets are given a new local identifier and DOI. This allows a user to see exactly on which datasets, and which versions of the datasets, analyses have been undertaken. It allows future users to redo old analyses after adding new data, and allows for a transparent reproducibility of any analyses using the database. All data are also attributed to their authors, the originating publications, and source databases or archives, and released under Creative Commons licensing (http://creativecommons.org/). The SEAD software will also be released under the GPLv2 with classpath exception licensing system (http://netbeans.org/gplv2-faqs.html for information about classpath exception) so that others may easily expand on the original development work. Instances of the database itself may be

downloaded by anyone from the project website (http://www.sead.se/downloads).

Quality Assurance and Data Cleaning

Standard data entry is currently performed through the downloadable SEAD application, which essentially duplicates the public database on the user's desktop, and initially stores newly entered data locally. The local database may be updated to the latest available public data at any time, and users may choose to submit their own data at will. This flexible synchronization system allows work in progress to be kept private while the user has access to the latest public database, and can thus analyze their data in the context of the latest global results (Neotoma uses a similar system, but where data on the public server can be placed under embargo until a set date). Prior to public release, submitted datasets and accompanying metadata are sent to a web-based clearing house for quality assurance by peer review. The clearing house vets the data for mistakes, questionable values, duplications, and missing metadata, in dialogue with the submitting user, and finally makes it available online. These three activities, data entry, clearing, and publication (Fig. 4), are performed in the same downloadable software, removing the need for the understanding of complex data structures at all but the developer levels. Maintenance of this software does, however, come with a cost, and migration to a simpler online system is in underway in order to adapt to the current climate of constant development platform and operating system updates.

Data Quality, Accuracy, and the Limits of Automated Harvesting

While much effort is expended on cleaning data, mistakes inevitably occur. The users of any database should always ensure they critically evaluate the data they use, especially in terms of its suitability for the task at hand. Even cleaned data can be problematic if it is used without considering its origins and the implications of these. It is possible, for example, through a few simple queries and a bit of work in a spreadsheet, to extract the dates of the earliest find of any species with records in SEAD. Figure 3 shows these data for the grain weevil, *Sitophilus granarius* L., an important pest of stored products historically and today. SEAD contains 164 records of the species from archaeological sites in Europe and the Near East, with the

Strategic Environmental Archaeology Database (SEAD), Fig. 4 An outline of SEAD's data management paths, showing the three-tier system for (1) data entry, (2) quality assurance, and (3) publication

oldest finds associated with deposits at Atlit Yam in Israel. An examination of the dates in Fig. 3a shows that there are clearly some issues with the data stored in SEAD (see figure text), a consequence of the limits and focus of the published sources. A paper on insects in Iceland listing finds from the medieval period may not necessarily explain that the medieval period in Iceland starts around AD 1100, as opposed to the more general fifth-century understanding of the term from a broader European perspective. Clearly the use of such chronological periods requires their geographical relevance to be specified (or separate periods defined), and SEAD, along with many other archaeological databases, needs to address this fact if incorrect conclusions, drawn from the naïve use of the data, are to be avoided. Figure 3b illustrates what happens if the *S. granarius* dates are taken at face value, and used to create a surface representing date of establishment of the species over Europe. Unfortunately, the map is of little use, due to the skewed distribution of sites, and more preprocessing in terms of site selection and grouping would be required before the surface reflects the current state of knowledge, as expressed more qualitatively in Fig. 3c. The modern occurrence data provided by GBIF (2017; Global Biodiversity Information Facility, http://www.gbif.org) is shown in Fig. 3d to show that our quantitative knowledge of the species distribution at the present day, as far as our databases are concerned, is little better than that for the fossils.

The ceramic geochemistry (thin section) data available through SEAD provides an interesting insight in the quantification of potential data cleaning losses when dealing with legacy data. An Excel file with 5098 rows and 78 columns of analysis results, collated from records of over 40 years of work, was submitted by KFL (Table 2) for ingestion into SEAD. Of these, and after a considerable amount of data detective work, only 3499 rows were evaluated as being of good enough quality for ingestion into the database. (All of the intermediate stages in the evaluation of these data have been archived for future reference).

Future Directions

While an increasingly large number of archaeological, paleoclimatological, and paleoenvironmental research projects include multiple proxies, these are often interpreted independently. They also tend to be published either in different journals from the archaeological results or as a series of independent lab reports appended to the main archaeological report. By collating data from these, and providing proxy-independent querying system and data aggregation tools, it is hoped that SEAD will promote a more integrated approach to environmental reconstruction, especially at the multi-site level. It is also hoped that by providing the tools for spatially and chronologically aggregating data from multiple proxies, the often contrasting signals from different proxies may be interpreted together so as to illuminate the complex nature of reality rather than simplifying the past by discarding less easily interpretable results.

Databases gain more potential through links to other databases, and the ability to simultaneously interrogate both modern and fossil biodiversity data would be a powerful tool for understanding modern biodiversity patterns, faunal origins, and human impacts and provide key data for predicting the implications of future climate and environmental change. Closer cooperation with biodiversity portals is therefore desirable, an ideal situation being that international maps of fossil and modern species distributions could be overlain. For much of the available modern biodiversity data, the resolution and quality is as yet too poor to be of use in paleoenvironmental reconstruction (see Fig. 3), and many researchers even maintain their own, disconnected, databases for research in ecology (especially as numerous GBIF records give occurrence coordinates which are museum collections rather than sampling locations). Many national archives (e.g., Artdatabanken 2017; BRC 2017), however, may hold appropriate raw data which is in the process of being uploaded to international portals such as GBIF (2017), and there is potential for a significant improvement in the extent and quality of the

data if sufficient funds are invested in trained quality control experts.

Past and present changes in biodiversity and landscapes cannot realistically be investigated without reference to human, and thus archaeological, impacts on the landscape. Paleoenvironmental databases and the software for interacting with them are therefore key components in the process of integrating the wide range of fields required to effectively study these issues (e.g., Brewer et al. 2012). They also provide us with empirical evidence to back the *scientific facts* of the human component in climate change and species extinctions. Future collaboration between SEAD and the Swedish LifeWatch (http://www.slu.se/en/subweb/swedish-lifewatch/) consortium, with an aim toward integrating past and present biodiversity data, and developing tools for their analysis and visualization, will hopefully improve the possibilities for more integrated research, and true socio-ecologically orientated projects.

The US-led, National Science Foundation-funded, but international DataArc project (http://www.data-arc.org) aims to build a portal which will allow users to discover data across multiple databases, through the common use of space, time, and "concepts" (see Strawhacker et al. 2015). The latter of these represents a new approach, and involves the construction of an intermediate layer which allows for the tagging of data elements, or indicators, in the different systems according to a common conceptual model stretching across the humanities and natural sciences. Naturally, not all of the databases will be mapped to all of the concepts, but the approach allows for some interesting thought exercises, such as the relationship between literary water wizards and geological flood deposits in Iceland, or the potential to look for hide eating beetles as a proxy for parchment preparation. The concept-linking model takes the construction of portals beyond the more common (but necessary) data indexing approach, which is more appropriate for cataloguing and exposing archives than creating research tools for transdisciplinary science. It could be that such ideas represent the difference between systems for normal science and those which may encourage paradigm shifts; both of which are needed.

Closer collaboration with archaeological database management systems and authorities is always desirable, and discussions are ongoing to ensure compatibility with and promote the joint use of the Swedish National Heritage Board's databases and online services, especially the sites and monuments records (FMIS 2017). There has, as yet, been little movement on this front, and the lack of time and funds for joint tool development is a hindrance to progress.

SEAD is intended to be an international resource for any science where paleoenvironmental or paleoclimatic data are of interest. The project aims not only to become a more securely established link in the archiving of these data but also to provide a set of well-respected online tools for their analysis, and be instrumental in the development of new theories and methods for examining past climates, environments, and human activities. In order to achieve these goals, SEAD needs users, and it is hoped that the project's open-access policies, along with a large database of linked-open data and efficient tools, will encourage a broad and productive audience. The VISEAD project is designed to help expand the usefulness of SEAD for archaeological consultancies and government bodies involved with cultural heritage data (e.g., county councils and transport authorities). The SEAD team and its partners are actively committed to seeking funding and collaboration for projects where the system is either used as an archive or analysis tool, as well as developing the existing tools further.

SEAD's initial development phase ended in 2013, after which it entered a routine management phase where data entry, support, and quality assurance have prioritized over development. In 2017–2018 the existing platform and interfaces have been overhauled in order to cater to changes in software environments, new user requirements, and an expanded data scope. Further development projects are planned, including the development of advanced online tools, teaching tools, inter-archive connectivity and Arctic archaeology, and cultural heritage. As an open-access project,

SEAD actively encourages the independent development of tools using the database.

Stratigraphy in Archaeology: A Brief History

Leandro D'Amore
Escuela de Arqueología UNCa, San Fernando del Valle, Catamarca, Argentina

Introduction

The story told here is a summary of some of the actions that gave form to the scientific field that is archaeological stratigraphy. A story whose true nature lies latent, overlaid by a superficial enumeration of chronological dates, superimposed and outdated by social events, an encyclopedic history records the process of development of the current use of stratigraphy in the majority of archaeological investigations. The reading of this history should be viewed from two perspectives which crosscut this narrative. The first relates to the numerous conflicts that reflect a criticism of modern science. The second refers to a history of excavation techniques that define a decisive point in the scientific nature of archaeological practice.

Historical Background

In the seventeenth-century Europe, a uniformitarian vision of Earth's geological history gave rise to the argument that stratigraphy could be explained from principles of superpositioning and chronology, from types of sediment and forms of strata, or through association with fossil remains. This was a naturalistic model of stratigraphy, which gained strength halfway through the nineteenth century when Lyell proposed his methodology for determining the relative sequence of geological strata based on the study of its fossil remains. After this, European archaeology appropriated the model in order to date archaeological strata by the types of products they contained, treating certain diagnostic artifacts as *guide fossils* (Carandini 1997; Roskams 2003). (There are two exceptions to this statement: (1) Towards the end of the eighteenth century, Jefferson (the North American President) is purported to be among the first to use a stratigraphic view in an archaeological context, in reference to a funerary mound (Wheeler 1995 [1954]); and (2) in an 1816 publication, Smith announces the stratigraphic ordering of fossils according to the strata they belonged to, carried out in excavations in the south of Great Britain, using the term "*stratum*" for the first time (Harris 1991; Wheeler 1995 [1954]).) In that context the meaning of stratigraphy was related to chronological problems in the historical and evolutionary interpretation of prehistory. In the dawn of the twentieth century, all of these ideas crossed the Atlantic, particularly to North America and Mexico, forming the basis by which stratigraphy would be conceptualized as a modern excavation method that would facilitate temporal interpretation and assignation; for many, this meant a revolution in the archaeological vision of the past, arguing in favor of the first New Archaeology (Browman and Givens 1996; Lyman and O'Brian 1999; Schávelzon 1999).

From these first events, the study of stratigraphy in archaeological deposits would always be dominated by both a naturalist vision oriented by the sedimentary content and an instrumentalist vision using it as an excavation technique. Both perspectives were based on a single naturalist-instrumental strategy, in which the use of stratigraphy in archaeological contexts is justified as the only way to build an objective historical scientific knowledge of the past.

To better understand this historical view of stratigraphy, this entry will outline three distinct schools of thought. The first is linked to archaeology's initial approaches towards introducing the study of stratigraphy: a distinctive vertical observation of the past, associated with particular excavation techniques. The second corresponds to the vision of geoarchaeology, which

favors the *sedimentary content* of stratigraphy. And, finally, the third is generated from the perspectives of Wheeler and Harris around the study of *interfacial forms and stratigraphic relationships*. In all these, stratigraphy is perceived as representing a temporal metaphor for building archaeological chronologies, regardless of the subject matter used in those sequences (set of artifacts, sediments and interfaces). (The order of these three currents of thought is not a precise temporal sequence, seeing the proposals of Wheeler as contemporary with the perspectives of the first trend and the proposals of Harris as on par with those of geoarchaeology. Nonetheless, each of the three conceptions has their temporal and geographic reference point: the first began towards the end of the nineteenth century, waning halfway through the twentieth century; at first it flourished in Europe but was methodically instituted into the American scene. The second train of thought was established in North America and was becoming known at the start of the 1960s; and the third current occurred in the United Kingdom in the middle of the twentieth century. Development of the last two ideas occurred unevenly in different parts of the world (the Harris Method excelled in the European continent and certain parts of Asia, while geoarchaeology spread across the American continent), and they spread as opposing points of view relative to each other, a position which continues to this day (Waters 1992; Holliday 1992; Harris et al. 1993; O'Brian et al. 2005)).

Key Issues/Current Debates

Verticality

Stratigraphy rapidly came to be associated with the theory of the linear evolution of species, marked by the fossils, which meant interpreting the archaeological discoveries contained in the strata as belonging to distinct stages of human evolutionary development. This perspective was strongly criticized in North America by historical particularism, especially for its use of stratigraphy as evidence for the progress from primitivism to civilized phases. The debate turned on whether the stratigraphic succession of archaeological discoveries reflected stages of evolutionary development, but the criticisms and queries were not directed at the evolutionary model but at its application in case studies in North America (Lyman and O'Brian 1999; O'Brian et al. 2005). This was a transition period for the strategies and modes of field work, in which importance was being placed on the context of the discoveries (the deposit, the stratum, the cap, the bed, the arbitrary cut), and not just the providing of samples intended for museums (Lucas 2001; Roskams 2003). In Europe, the meaning of context was related to problems of the interpretation of prehistory (Carandini 1997); while across the Atlantic, in North America and Mexico, it was related to an excavation system which gave scientific validity to the explanations of archaeologists (Browman and Givens 1996; Schávelzon 1999). (The considerations of Pitt-Rivers and Petrie are also pertinent. Their work in Europe and the Middle East stimulated interest in America concerning a sectioning method which would consist of excavating trenches on archaeological sites following arbitrary levels; the recovery of artifacts, innovating a three-dimensional recording method for each discovery and positioning them in projection and in profile in the drawings; and the construction of typologies using seriation (Lucas 2001).) It was in this latter research area that stratigraphy was thought of as an analytical tool for an archaeological method and as such there was a gradual awareness of a change in the techniques for excavating stratified deposits.

The study of stratigraphy was introduced by observing the profiles exposed on the walls of excavated trenches or vertical columns of sediment (sample cores). From diagrams of those profiles, the content was observed by levels, interpreting similarities and differences in the overlaying of objects, fossils, and strata. The aim of these observations was to specify the chronological bearing of archaeological cultures in sequences of horizons, but they did not focus on questions of cultural change (Lyman and O'Brian 1999). Stratigraphy was identified with a structure of simple vertical units, from which discoveries were perceived between vertical limits given by

discrete and real entities (arbitrary levels or natural strata), rather than from a possible fortuitous cause of sedimentation. These vertical units were not considered geological, but were used as units of archaeological deposition that were incorporated into a time line of the history of the site. In particular, stratigraphy was thought of as an analytical tool from which inferences were obtained once excavation is finished; it consisted of post-excavation observations or ex post facto interpretations, where the reading of stratigraphic profiles confirmed data from the excavation. From this point the systematic incorporation of stratigraphic method into field practices was instituted (Praetzellis 1993; Browman and Givens 1996; Lyman and O'Brian 1999; Schávelzon 1999), signaling the metaphorical use of stratigraphy to represent the passing of time in the constructive history of an archaeological site. But paradoxically this vertical vision of stratigraphy was not sustained by any stratigraphic excavation. (The excavation technique associated with this stratigraphic view was founded on an arbitrary strategy defined by metered levels of a predetermined thickness. The objective was to identify the different depths of the artifacts, without depending on any distinction associated with observation of the caps or the strata during the excavation. In opposition to [this] strong emphasis on the metric [measured], another excavation technique was proposed which consisted of dividing the deposits according to the natural strata that constitute it, such as sand, ashes, gravel, and other types (Praetzellis 1993; D'Amore 2002)).

The vertical view of the stratigraphic superposition was verified and reinforced by diagnostic chronological sequences of pottery groups, developed using the seriation technique applied to data obtained from excavations (Praetzellis 1993). The seriation of ceramic styles was considered a form of stratigraphic vision (e.g., in the proposals of Kidder; O'Brian et al. 2005), but the vertical vision of the profile and the horizontal vision of the excavation remained separate instances of interpretation. All this simplified the idea of stratigraphy to the superpositioning of artifacts and, principally, to a visible, analytical superpositioning related to the requirements demanded of archaeology as a positivist science: to resolve questions of diachrony and cultural change.

The use of the notion *cultural stratigraphy*, which defined an arbitrary stratigraphy of occupation phases and cultural components, was associated with the term *stratification* without considering the stratigraphic superposition relationships. The process by which the physical structure of a site is separated and organized in strata or caps, horizontal cuts of a predetermined thickness, was not found to have an analytical correlation with the term *stratigraphy*, which would be the interpretation of the deposition sequence and of the stratigraphic relationships of superpositioned strata (D'Amore 2002). This methodological tendency created a permanent conflict by separating into two analyses that which would be only one field of study (superposition relationships). Despite the many complications of these instrumental and naturalistic representational proposals concerning stratigraphy, it was from both its criticisms and the truths attributed to it that a foundation was laid for the later theoretical and methodological premises of two subsequent schools of thought. In this way, the concept of stratigraphy was gradually introduced in relation to its content, but only because of its archaeological or cultural inclusions, and not the contents of the sediment or any other operative entity such as the stratum, coating, or facies. (Maybe an exception would be the idea of sedimentary content that was held in the cases that came from an artificial excavation through natural layers).

Content

In its opposition to historical–cultural procedures, processual archaeology disregarded archaeological stratigraphy (O'Brian et al. 2005). So that, fearful of once more creating a mistaken and hasty causal relationship between sediment and culture, it resolved to incorporate geology in an interdisciplinary way, in order to take care of the excavation sediments, on the one hand, and the explanations of cultural processes in the dynamics of the past on the other (Lyman and O'Brian 1999; O'Brian et al. 2005). In this intellectual context, oriented by an ecological, geographical, and

environmental perspective, geoarchaeology was shaped. A subdiscipline viewed the archaeological record as a natural deposit that incorporates, in its sedimentary matrix, the cultural material of successive past human occupations (Butzer 1989 [1982]; Waters 1992); and it raised awareness of a new way to explain the contextual association of sedimentary particulates in archaeological deposits (Stein 1987). (This arises from the uniformitarian premise that the archaeological record has been formed by the same processes that molded the natural landscape (Butzer 1989 [1982]; Holliday 1992; Waters 1992, Waters and Kuehn 1996). The idea beneath this logic is the following: the terrestrial landscape changes constantly, but the laws of physics and chemistry that govern the processes are immutable over time. This uniformitarian principle is based on the interpretation that those absolute processes produce uniform attributes in past, present, and future strata. Sedimentology presupposes that one can reconstruct the processes that formed ancient sediments, because the forces they are subjected to in the present operated just as uniformly in the past (gravity, thermodynamics, fluid dynamics)).

The unit of analysis was the sediment, which is incorporated through the study of the sedimentary particulates, arising from the sedimentological vision of geology. The stratigraphic interpretation is fixed in a rigorous objective description of the differences in sedimentary content of the archaeological site deposits; it consisted of a sedimentological study that based itself in nomenclatures of geological stratigraphy (Gasche and Tunca 1983; Farrand 1984; Stein 1987). The formation of archaeological sediments is thus reduced to the study of human impact over natural soil formation (Butzer 1989 [1982]; Holliday 1992; French 2003). From the depositional study of sediments (sedimentology) and postdepositional study given for soil formation (pedology) comes the interpretation of the stratigraphy of an archaeological deposit (Holliday 1992; Waters 1992). The stratigraphy of an archaeological site was understood to be constituted of cultural remains (surfaces of occupation) buried by a sedimentation that was, almost always, considered natural (burial between high and low rates of natural sedimentation). Consequently, the archaeological record is found preserved in a stratification of rock sediments (lithostratigraphy), in a soil or paleosoil horizon (pedostratigraphic unit), and also sedimented between the contact of a sediment and the surface of a soil (Waters 1992; French 2003). In this specialized literature, stratigraphy had a secondary application, complementary to sedimentology, where the key was explaining an archaeological site's sedimentation through evidence derived from the geomorphological formation of the landscape where the human settlement was located.

The program of geoarchaeological study was supported by objectives postulated by Schiffer (1987) to investigate processes of formation, preservation, and destruction of archaeological sites: the study of the physical and chemical properties of the soils and sediments, incorporation of ethnographic and comparative studies of modern sedimentary deposits, and the study obtained by experimental replication of sedimentary processes. The driving importance of formation processes meant that geoarchaeology would concentrate on examining the formation of artifact content in the archaeological record, as regards the N (natural) transformations (Stein 1992, 2001). (Compression of the postdepositional processes of formation centers on environmental modifications to the archaeological remains, as defined by dispersion before burial, the postdepositional alteration, the geochemical modification, and even as far as processes that totally destroy the archaeological site. Within the range of site formation processes are included the geomorphological processes of the Late Quaternary associated with changes in the landscape that significantly altered or preserved, spatially or temporally, the archaeological record's evidence of human occupancy (Waters and Kuehn 1996).) From there followed an emphasis on relating a history of human interaction with the environment, to explain economic and ecological behaviors between episodes of environmental fluctuation. (This was the aim of the contextual perspective initiated by Butzer (1989 [1982]), by which he proposes a study of archaeology that hierarchically contextualizes three units of

analysis, the landscape, the sediment, and the artifact, and treats the cultural material as an indicator of the human being as a geomorphological agent in the sedimentary cycle of an archaeological deposit).

One stance even included establishing as a problem the lack of standardization in the stratigraphic method, which could have reduced the pejorative conflicts implicated in using many chosen criteria to form a nomenclature (Farrand 1984; Stein 1992). The solution was to adopt a stratigraphic nomenclature associated with a standard excavation procedure, which would permit a precise and objective naming of distinct sedimentary units and would mediate over a plurality of case studies.

For geoarchaeology, this nomenclature represented a classification tool appropriate to the scientific view of archaeology, because the principal units of stratigraphic analysis were distinguished using lithological criteria based on direct observation of the sediment's tangible attributes and fixed in descriptions that were independent of any interpretive discussions about meaning (Stein 1987, 1992; Courty 2001).

The objective was for the stratigraphy of an archaeological site to be observed as multiple sequences independent from one another (lithostratigraphy, ethnostratigraphy, and chronostratigraphy) but analyzed under a singular standardized nomenclature (Stein 1992). (The stratigraphic classification codes of geology, and those created for geoarchaeology, are supported by a sedimentological and pedological classification above any other type of distinguishing criteria. The fundamental unit is lithostratigraphic, while the ethnostratigraphic and chronostratigraphic units are lithological units grouped firstly by type of cultural content and then by correspondence to a particular time period (Stein 1987; Lucas 2001). The lithostratigraphic units are hierarchically more important than the other two, because they result from rigorous objective descriptions of the sedimentary particulates' attributes (they are observational) while the remaining units are defined by interpretation (they are inferential) (Gasche and Tunca 1983; Stein 1992)).

The use of this classification system meant that, in terms of objective rigor, artifacts would be considered as sediment, or one more particulate of sediment (in essence they continue being *fossils*), the people would be biological agents of sediment formation, and prehistorical and historical time periods would be geological eras. In the beginning it was assumed that archaeology did not require theoretical and methodological premises just for studying stratigraphy; at the most it would require different units of analysis on a smaller scale (Farrand 1984; Stein 1992). This was because it was thought that if they set up a separation, with one archaeological classification and another geological, there would be conflict when carrying out correlations between the microstratigraphy of an archaeological site and the regional geological stratigraphy (Waters and Kuehn 1996).

For geoarchaeology, in the analytical terms of sedimentary *content*, stratigraphy was becoming established as a study of the vertical order of physical contacts (superpositional relationships) between sediments and soils (observable physical units) and recorded by the order of deposition (aggradation) and stability and erosion (degradation). The different types of elements that make up the cultural material were conceived as archaeo-sedimentary particulates or intrusive archaeological inclusions of the natural sedimentary matrix (Stein 1987). The cultural material was treated as if it were one more component among others: physiogenically and biogenically (Butzer 1989 [1982]). Anthropogenic sediment, from its process of sedimentation (or stratification), was considered natural geological sediment (Farrand 1984, Stein 1987). In this context, archaeological sediment was defined as one which contains particles that are affected and altered by cultural processes and therefore contain information about human occupational activity (Butzer 1989 [1982]; Stein 1987). Also, sediments were different when not affected by human beings but could possess archaeological inclusions among its particulates. Various names were given to this category: anthropogenic facies, anthropic soils and sediments, anthrop-soils, archaeo-sediments, anthropic epipedon, cultural

cap or layer, archaeological levels, etc. All those terms try to be empirical in the sense that they manifest the material existence of human intervention at the site. Specifically, the archaeological site was defined by *aggregates of sedimentary particulates*, and those aggregates were defined as deposits distinguished by content or homogenous physical properties, of which one could recognize behaviors and patterns at the artifact level and depositional processes at the level of the sedimentary particles (Schiffer 1987). (Each deposit would be the result of a depositional event that made up the sediment's history: the source, the transport agents, and the deposition environment (Waters 1992). The depositional event is a sedimentation formed under constant physical conditions during a specific interval of time (Courty 2001)). The concept of *deposit* and its extension to the category of *sediment* (the content of the deposit) were considered to be the minimal and basic empirical–analytical contexts for identifying and recording exposed excavation profiles.

Forms

Ever since the school of thought begun by Mortimer Wheeler (1995 [1954]) but consolidated and deepened by Edward C. Harris (1991 [1979]), the unit of analysis was no longer the *content* in terms of the sediment or deposit but the *form* of the stratigraphic units as interpretation of the interfaces. More importantly, one no longer dealt with the isolated interpretation of stratigraphy and its archaeological content, but with an understanding of stratigraphy and its archaeological nature as part of one feasible entity to be studied: *archaeological stratigraphy.*

Incorporation of the term "interface" to designate the contact and relational surface that all stratigraphic units have with one another has prompted a relational study of stratigraphy: the interpretation of types of stratigraphic relationships and their configuration in an archaeological sequence diagram (the Harris Matrix). Principally, the idea of an *archaeological interpretation* of the stratigraphy was established, one that would not be restricted to the nature of sediment and artifact relationships but would account for the many stratigraphic relationships interpreted that were social relations between actions and practices produced at a certain moment during human occupation of the site.

Harris' intellectual approach gained meaning with the idea of denominating an archaeological stratigraphy in its own formal terms, applied only to archaeology (Lucas 2001; D'Amore 2002). His proposal to define four basic principles for archaeological stratigraphy (Harris 1991 [1979]), adapted from the principles of geological superpositioning, began a race by arguing: (1) in favor of identification and interpretation of a stratigraphy of an archaeological nature independent from a geological superposition and (2) the introduction of stratigraphy into a body of theory which encompasses the relationship dynamic of such singular deposits as the archaeological. (Harris had in mind a scientific tool to particularize archaeology as a distinct discipline in two ways: (1) that archaeology would consciously shake loose from certain realities that only made sense for geology and (2) that would question the theoretical reach of certain problems and interpretations surrounding the practice of archaeological excavation (Harris 1991 [1979])). Many supporters of these theoretical–methodological proposals went on to pronounce in favor of a paradigm that treated archaeological stratigraphy as a science in its own right (Harris et al. 1993; Carandini 1997; Roskams 2003). The paradigm took form from six distinctive aspects.

First, it facilitated the introduction, to the stratigraphic record, of archaeological features that had previously not been considered as stratigraphic units, archaeologically speaking, such as pits, ashes, any soil disturbance (chemical or physical), ramparts, depressions, walls, and other features (Harris 1991 [1979]; Lucas 2001).

Secondly, construction of an archaeological stratigraphic sequence in the Harris Matrix format implied a specific stratigraphic excavation process. This meticulous stratigraphic methodology differed from other types of excavation, which was along arbitrary, naturally occurring levels associated with recording the sections, cuts, and exposed profiles; this will gradually be replaced by the introduction of an *open area* strategy and a

record by singular context using diagrammatic plans (Barker 1977; Praetzellis 1993).

Thirdly, it gives importance to the horizontality of archaeological stratigraphy, specifically the incorporation of a horizontal view of the projected surface outline of the interfaces. This broke the persistent norm imposed by the vertical perspective of drawings and sketches of exposed cores in profiles, sections, and stratigraphic columns (Harris 1991 [1979]). Deciphering the formation sequence of the archaeological deposits came to depend on the interpretation of the stratigraphic relationships, not from mere observation of the exposed profiles but from how those relationships are recorded while excavating, starting from their horizontal extent in space and time.

Fourth is the configuration of archaeological stratigraphy in a multilineal diagram known as the *Harris Matrix*, which expounded a methodology of graphing on a two-dimensional plane to show distinct types of stratigraphic relationships across time, as a three-dimensional representation, and to deal with the various post-excavation problems of stratigraphic interpretation (Lucas 2001; Roskams 2003). (Relationships of superposition (A is behind and later than B; B is before and earlier than A), of contemporariness (A and B belong to the same moment of formation), and of equivalence (A is B) or, in any case, without a direct stratigraphic relationship.) The Harris Matrix consisted of a structure with the form and content of a sequence, where space does not appear to be bifurcated by the trajectory of the time, but that establishes a colligation of the verticality of time (sections) with the horizontality of space (record plans) (Harris 1991 [1979]; D'Amore 2002).

Fifth is the transforming basis of the Harris Matrix sequence in that it principally represents the stratigraphic nature of the superposition, before the topographic order, thus avoiding having to transfer, to the diagram, physical relationships between the units. Then, the archaeological stratigraphic representation came to be the interpretation of stratigraphic relationships, the symbolic dimension of relative time, and not directly an empirical or realistic record of the physical–topographic superposition (Harris 1991 [1979]; Carandini 1997; D'Amore 2002).

Sixth, and most important of all, was the interpreting and correlating of *interfaces* as separate circumscribed units in an archaeological stratigraphic sequence (Harris 1991 [1979]). (A first approach to the idea of *interface* was Wheeler's proposal to excavate following *the natural contour* of the superpositioned strata and to adopt specific criteria for drawing irregular interfacial lines; this type of record was called the *Wheeler-Kenyon System of Archaeological Stratigraphy* (Harris 1991 [1979]; Lucas 2001). However, the visual representation of the interfaces played a second role, given that they were not recorded with a number, as what was done with the strata and its contents (D'Amore 2002). Otherwise the interfaces would continue to be observed and recorded solely from the verticality of the sections and profiles). In its analytical correlation with the excavation record, the interfaces were the surfaces of the horizontal and vertical strata equal to its total area (surfaces of positive accumulation) and were also the cut or extraction surfaces of the preexisting stratification in the sedimentary matrix (surfaces of negative destruction, or *interfacial elements*). (In geology, in the study of natural soil formation, the positive surfaces are associated with beds, deposits or formations, and the negative with discontinuities (Butzer 1989 [1982]; Stein 1987; Waters 1992). In their stratified state, these surfaces remain semiconsolidated and somewhat stable compared to the dynamics of being exposed to the elements during occupation of the site.) In its interpretative correlation, the surfaces were in direct contact with the gradual formation of the strata. Once these interfaces, through a process of stratification, became buried by other strata and incorporated into a sedimentary matrix forming a stratigraphy, they became the possible interpretive correlation of a level of occupation on which took place human actions and practices (Harris et al. 1993; Haber 1996), or the final extension of a sedimentation and natural degradation, in a given moment of site formation (Schiffer 1987; Carandini 1997). From this view of stratigraphy, the artifacts as much as the sediment's particulates were bound by the interfacial limits of the stratigraphic units; and, furthermore, in an archaeological site, the interface was a much more numerous stratigraphic unit than the strata

(Harris et al. 1993). Therefore, the character of the interfaces was the principal unit of analysis for constructing a sequence in terms of the Harris Matrix, and not the artifact or sedimentary content of the deposits. Harris and some of his supporters defined the interfaces together as units that denote surfaces *without content* (neither artifacts nor sediments). Unlike a stratum of positive deposition, the interface did not possess depth or substance (Harris 1991 [1979]; Lucas 2001), but did represent time and the stratigraphic relationships. Thus, the interfaces were not identified by their material content, but because they were *action surfaces*, of either deposition or extraction (Haber 1996; D'Amore 2002). Here arose a new way of thinking about stratigraphy, no longer founded in the nature of the sediment, but in the action that produced it, by humans or by nature.

In this way, it was recognized that even when archaeological stratigraphy was a "*heuristic device,"* it allowed, theoretically and methodologically, the definition of patterns significantly linked to human action and natural events, at the level of superposition of stratigraphic units as much as from the cultural content. Arising from this way of thinking, comprehension of an archaeological site began to view it as a palimpsest of action and discrete events. The archaeological site was fractioned into units or contexts that were excavated according to their position and stratigraphic relationships, but it was being defined by limits in time and space, as simple actions and events that leave a positive record (stratum) and a negative one (the cut). Archaeological stratigraphy was no longer a mere repository of objects, of cultural groups or of a direct normative representation of cultures, or cultural epochs; neither did it deal only with overlaid sedimentary caps. Rather, it was conceived as a deposit of actions and events which, given its relationships, form part of a history or histories that can involve material behaviors or leading patterns of sedimentation, representing sequences of rhythms and natural and cultural changes. (Harris' principles of archaeological stratigraphy were well received in the realm of the formation processes of Schiffer (see preface in Harris 1991 [1979]). With the theoretical–methodological framework of the Harris Matrix, the formation processes obtained a scientific rigor, supported by a type of archaeological excavation practice. The leading alternative was no longer based solely on a different form of building archaeological theory, but from that, the theoretical entities of formation processes tackled their corresponding material in the archaeological sites, aided by the working categories of the excavation record proposed by Harris: strata, interfaces, and interfacial elements. More importantly, these units of study proved to be potential actions and events (natural and cultural) visually identifiable or materially represented in the context of archaeological practice).

Future Directions

Within the archaeological discipline, stratigraphy has become a structure of thought regarding time and linearity, and as such it conditions and restrains the archaeological interpretation of the past. It is a modern metaphor for representing historical time (narrative) and physical time (relative chronology), but this metaphor would be nothing if stratigraphy were not structured by the modern belief in *succession* in a *sequence*. In the daily tasks of archaeological practice, time is naturalized by the temporal metaphor of the sequence and of the stratigraphy: the passage of time is both vertical and sequential.

Stringer, Chris

Louise Humphrey
Department of Earth Sciences, The Natural History Museum, London, UK

Basic Biographical Information

Chris Stringer studied Anthropology at University College London and subsequently completed his Ph.D. in Anatomical Science at Bristol University in 1974.

He has worked at the Natural History Museum in London since 1973, where he is now a Research Leader in Human Origins and he is also a Visiting Professor at Royal Holloway, University of London. Stringer was awarded a D.Sc. in Anatomical Science by Bristol University in 1990.

Major Accomplishments

Chris Stringer was elected Fellow of the Royal Society in 2004, Fellow of the American

Association for the Advancement of Science in 2011 and Honorary Fellow of the Society of Antiquaries in 2010.

For his Ph.D., Stringer studied Neanderthal and anatomically modern human crania in collections across Europe and the Middle East, concluding that anatomically modern humans had not evolved from Neanderthals but had migrated into Europe replacing the earlier Neanderthal inhabitants. As a result he was an early proponent of the Recent African Origin model (also known as Out of Africa) of human evolution which holds that anatomically modern humans evolved in Africa and subsequently migrated across the globe replacing any previous archaic inhabitants.

Recent genetic evidence reveals that living people carry small amounts of archaic DNA and that this is regionally variable, consistent with an African origin for modern humans and limited interbreeding with archaic groups at a local level. Stringer has recently proposed a new model for modern human origins in Africa, which has been termed "coalescent African origin".

Stringer has also had a major role in promoting and collaborating in efforts to produce a sound chronological framework for modern human origins by establishing new dates for key specimens and archaeological sites. This has involved working with specialists in radiocarbon, luminescence, electron spin resonance, and uranium-series dating techniques. Stringer has directed or co-directed excavations at sites such as Westbury-sub-Mendip and Gough's Cave in the UK and Ibex, Vanguard, and Gorham's Caves in Gibraltar.

Since 2001 he has directed the Ancient Human Occupation of Britain (AHOB) projects, bringing together a team of paleontologists, archaeologists and earth scientists to investigate successive human occupations of Britain and to reconstruct the environments in which these early people lived.

In 2005, the AHOB team revealed new evidence suggesting that humans reached Britain about 700,000 years ago based on the presence of worked flint at a site in Pakefield, Suffolk dating to Marine Isotope Stage 17.

Since then the discovery of more than 70 flint tools and flakes from Happisburgh in Norfolk has pushed back the date for the earliest occupation of Britain and northern Europe to more than 800,000 years.

Stringer has taken a leading role in co-organizing conferences such as:

- "The Origins and Dispersal of Modern Humans" (Cambridge 1987)
- "The Origin of *Homo sapiens* and the Impact of Science-based Dating" (Royal Society 1992)
- "Gibraltar and the Neanderthals 1848–1998" (Gibraltar 1998)
- "Human Origins" (Cold Spring Harbor 2000)
- "The Human Revolution Revisited" (Cambridge 2005)
- "The first four million years of human evolution" (Royal Society 2009)
- "Culture Evolves" (Royal Society and British Academy 2010)

Stringer's books include:

- In Search of the Neanderthals (1993 with Clive Gamble)
- African Exodus (1996 with Robin McKie)
- The Complete World of Human Evolution (2005 with Peter Andrews)
- Homo britannicus (2006)
- The Origin of Our Species (2011)
- Lone Survivors: How We Came to Be the Only Humans on Earth (2012)

Structural Archaeology

Margaret Conkey
Department of Anthropology, University of California, Berkeley, CA, USA

Introduction

To write about the field of "structural archaeology" – where it comes from, what it does, and where we are now – means we must consider structuralism as an intellectual movement and how it impacted archaeology, although this is not all there is to it. It might seem at first that writing about structuralism in archaeology in these first decades of the twenty-first century can only be a historical commentary on an approach, a theory, and a method that we have gone through and beyond. Some researchers today might opine that a structural archaeology has been bypassed by other approaches and subsequent critiques. There are even terms for what developed supposedly "after" structuralist thinking and research, namely, post-structuralism and even structuration. And there are those who might suppose that even these afterlives of structuralism are faded and discarded paradigms and frameworks for the analysis and interpretation of archaeological materials and situations. Furthermore, some would even argue that all of these approaches were never "mainstream" archaeology or, if undertaken, produced only transitory results that have not really stayed with us. But in reviewing what structuralism has been for archaeology, the case can be made that its influences have been more far-reaching than one might suppose, even in the reactions and rejections of what some structuralist research might appear to be. Robert Preucel (2006: 95) even takes the view that structuralism in archaeology can now be viewed as an "intellectual bridge spanning radically different theoretical programs." Indeed, we are not yet finished with a structuralist legacy and imprint on the archaeology of the twenty-first century.

In this entry, I consider what is meant by structuralism, both in general and especially structuralism in and for archaeology; the historical background to the structuralist movement (what Gellner (1982) called "structuralisme") and to its appearance in archaeology. In some ways, this account will be one in which we can chart the rise of structuralist concerns in archaeology, their impact or what I have called a structuralist "breakout" (Conkey 1989), and then what might be viewed as their "going underground" where they continue to undergird some research and remain a somewhat silent but detectable presence in how archaeologists work. As Alison Wylie (1982) pointed out so astutely in her still salient review and argument for the epistemological issues of structuralism in and for archaeology, archaeology must employ some form of structuralist analysis. From its inception, structuralist theory and analysis have been international in origin and scope, even if they are less manifest in those traditions of archaeological practice that have been primarily cultural historical in approach. But can we consider there to be – to still be – a structural archaeology?

Definition

To begin to cover the definitions and history of Structuralism, with a capital "S," as a major intellectual movement is a daunting task for the landscape of this movement stretches far and wide – from its core incubation in the fields of linguistics and the study of languages to epistemological if not ontological debates and treatises. In this discussion, I take the view that while there is a body of theory and philosophy called *Structuralism*, with its associated methods and analytical imperatives, we can also talk about "structural approaches" that do not necessarily accept all or most of high or "capital S" Structuralism,

especially that which is considered to be classic Structuralism. Many entire books about Structuralism have been written over the decades (e.g., Hawkes 1977; Pettit 1977; Eagleton 1983 among dozens), and anthropology has played a prominent role in the history and development of Structuralism especially through the scholarship of Claude Levi-Strauss (e.g., 1963) and his predecessors in French sociology such as Durkheim and Mauss. Critiques of Structuralism have also been strong in anthropology (e.g., Sperber 1974; Fabian 1983), but as the archaeologist, Chris Tilley (1990), pointed out, Levi-Strauss is indeed a required reading, especially for an archaeology that takes seriously material and visual culture.

As Robert Layton writes in his most useful and admirably succinct chapter on "Structuralism and Semiotics" in the *Handbook of Material Culture*, these two approaches "provide ways of studying human cognition and communication" (Layton 2006: 29). As such, as we will see, there has been some disdain or dismissal (or just plain an ignoring) by many archaeologists who do not believe that archaeology can "recover" cognition or communication of past societies and perhaps certainly not any "meaning," but this is to jump ahead in our account. Structuralist assumptions include a core idea that there are underlying cultural premises to cultural practice and production and that these can be discovered by the analyst. In classic structural thought one might anticipate that the working out of specific cultural structures drew on some universal concerns, usually expressed in the form of binary dualisms, such as male/female, dark/light, wild/tame, public/private, and life/death – dualisms that were often mediated through various cultural acts, productions, or practices, such as myths, or, in the case of Leroi-Gourhan's well-known structuralist study of Paleolithic cave art (Leroi-Gourhan 1965), through image making or art. In this pathbreaking analysis, Leroi-Gourhan was attempting to identify the underlying structures and even "grammars" for the making and placing of specific images of animals or signs in the caves. While recognizing that the meanings of these structural manifestations are not immediately (or ever?) available to us some 20,000 years later, Leroi-Gourhan links the underlying structural generation to cultural mythologies, leading him to suggest that we could understand the patterning of Paleolithic cave art as a kind of "mythogram."

Of course, Structuralism is much more complicated than seeking and finding universals, polarities, and mytho-grammatical structures. Deep debates abound in the literature about fundamental assumptions and subsequent analytical methods by which Structuralists proceed. For example, Gellner (1982) probed this notion of "structuralisme" and its methods with such issues as just how the relevant polarities are to be identified and confirmed: "Not only are the polar extremes (of a text) simply plucked out and then treated as somehow explanatory of the world that the users of said text live in, but no criteria are offered for how one is to identify the crucial polarities of a world from any old contrast that a willing and imaginative observer may locate in it" (Gellner 1982: 122). And he goes on to say, "A descriptive account of the spectra or polarities of a given society or language works with is *not* the same as a generative account of how these spectra are produced. In other words, one should not confuse, so to speak, descriptive or phenomenological structuralisme with a genuinely explanatory kind" (Gellner 1982: 123). So, while strongly critical, Gellner concludes that his criticisms "merely amount to a recommendation of caution in the application of these ideas to fields other than those in which they were originally fruitful" (1982: 123). When we survey the applications of structuralist concepts and methods as put to use in archaeology, we can evaluate them with such critiques and cautions in mind. As we will see below, the "plucking out of polarities" critique is not the only one that archaeologists should take seriously.

Historical Background

There is no doubt that structuralism and one of its handmaidens, symbolic analysis, was one of the more potent theoretical frameworks in the 1960s and into the 1970s in the social sciences and especially anthropology. Although many would

readily note that structuralism played an important role in the "turn" to more symbolic archaeologies of the 1980s, structuralism was also an important – but "underappreciated" – role in the development of the processual archaeology of the late 1960s and 1970s (see Preucel 2006: 93–121).

The question here is what is a structural archaeology, as this is a particular approach that first emerged most explicitly by the 1970s. In Anglo-American archaeology it might best be represented by the now-classic work of James Deetz (1977), although structuralism for archaeology was already put forth by André Leroi-Gourhan in France. To a great extent, the kind of structural approach put forth by Deetz (1977) was less concerned with the referential dimension – that is, how the structural patterns that underlay cultural phenomena impact back on the symbolic structure(s) – and more concerned with reconstructing the rules or cognitive patterns that undergirded expressions of folk material culture in early American societies, especially as manifest in such material culture as architecture, gravestone designs, and ceramic preferences. In this classic structuralist study, Deetz was able to take us to a "synthesis of the profound conceptual changes that occurred in America during the 18th century" (Leone 1986: 426) by using oppositions in Middle Virginia folk housing (as analyzed by Henry Glassie (1975)) and using them as a framework for the analysis of many classes of material culture including music. The oppositions included scattered/clustered, framed/open, and artificial substance/natural. With such an analytical framework, the connection to the Levi-Straussian structuralism/*structuralisme* is obvious.

The first sustained archaeological engagement with Structuralism took place at Cambridge University in 1979–1980. Ian Hodder and his students organized several graduate seminars, the goal of which was to interrogate the dominant views of archaeology, especially the Paleoeconomy school and the New Archaeology more generally. The participants in the seminar included Mary Braithwaite, Steve Cogbill, Sheena Crawford, Linda Donley, Ian Hodder, Paul Lane, Danny Miller, Henrietta Moore, Elen Pader, Mike Parker Pearson, Alison Sheridan, Chris Tilley, and Alice Welbourn, many of whom have gone on to distinguished careers. American scholars were also invited to give presentations including Meg Conkey, Susan Kus, Mark Leone, and Alison Wylie. This seminar resulted in the publication of *Symbolic and Structural Archaeology* (Hodder 1982a), a powerful critique of the New Archaeology. Despite the assertiveness of many of the participants, there was no clear agreement on the ways forward. As Hodder put it in his introduction to the volume, "there are many differences of opinion concerning, for example, the nature of ideology, the degree of determinancy in social changes, the types of structure that should be analysed, and the value of any reference to structuralism" (1982b: 14).

By the 1985 celebration of the 50th anniversary of the Society for American Archaeology, an edited volume was produced that had chapters on what were then considered core topics of contemporary archaeology. One chapter addressed "Symbolic, Structural and Critical Archaeology" (Leone 1986) attesting the recognition of these related but often quite different approaches as having come onto the scene enough in archaeology so as to be included in the volume, along with what might be considered more traditional topics, such as middle-range research, origins of food production, and hunter-gatherer archaeology. In Leone's 1986 chapter, he notes that a key feature of the three archaeologies that he discusses was the recognition and engagement with the idea that the material world (that archaeologists study) is not merely a reflection of past lives and cultures, but that there is a recursive quality to culture: the uses of cultural phenomena "shape our lives, and our lives would be shapeless without" them (Leone 1986: 416).

Thus, a structural archaeology might have several levels at which it would work. The Glassie-Deetz model, along with the Leroi-Gourhan model for Paleolithic cave art discussed above, has focused on trying to discern the underlying patterns or structuring principles that have generated what we can observe today, directly or indirectly, with (in the case of Deetz) or without (Leroi-Gourhan) informing texts. Other analyses

in archaeology were also provocative in making inferences regarding the codes or underlying generative patterns that might have produced material culture, ranging from regional wide settlement patterns and architecture, such as at Chaco Canyon in the US Southwest (Fritz 1978), to the making of designs on ceramics. In the latter studies, we would include the work of Dorothy Washburn (e.g., 1977) that identified underlying principles of symmetry for the generation of painted ceramic designs on Southwestern pots. At this level – the making of ceramic designs – Washburn has undertaken a formal analysis of structure and the structuring principles of design, with the suggestion that it is such underlying structures, more so than the use of the actual specific designs, or design elements, that has more potential to inform on the participation by ceramic makers in a "style" and as part of a related social group. Still others began to investigate the idea of practice inspired in different ways by Anthony Giddens and Pierre Bourdieu. Here we can mention the work of Linda Donley (1982) and the Swahili house and the studies of Mary Braithwaite (1982) on design among the Azande in Southern Sudan.

One key feature of these earlier structural approaches in archaeology that derives directly from more classic structural premises is the centrality of *relationships*. In fact, it has been argued by those who have been bold enough to survey the fields of structuralism and semiotics that structuralism induced, as a kind of first principle, a "momentous shift in the nature of perception" (Hawkes 1977: 17–8) that recognized that the nature of things lies not in the things themselves. Rather, the "world is made up of relationships" – those that we construct and then those that we perceive between things (Hawkes 1977: 17–8). Thus, for the archaeologist, it has been the relationships – between design elements on a pot, between architectural features and concepts of the individual, and between men, what and where they hunt and what they hunt with in comparison with women, what animals they hunt, and what tools they work with – that form the underlying network among "things" that have allowed insightful structural analyses. Seeking out the relationships, the patterns of the relationships and perhaps the cultural referents of the patterns have mobilized many a structural approach in archaeology. On the one hand, this search for/identification of structural relationships has allowed for a recognition and revelation of the connectedness and constructedness of human meaning, especially as a system of signs at a given point in time. Yet, paradoxically, especially for the archaeologist who so often is trying to track changes through time, this feature of the marked synchronicity of a structural analysis – at one point in time – reveals a serious flaw of structuralism, namely, that it was not a social and historical theory of meaning and meaning making; it has been "hair-raisingly ahistorical" (Eagleton 1983: 109). As we will see, with the rise of the 1980s theoretical influences both external to and within archaeology that turned attention onto agency, practice, and the "content" of the cultural productions more so than the "form," such a delimited approach as the more classic structuralist one was subject to serious critique.

Yet before we look at what emerged from structuralism and structuralist approaches to archaeological phenomena, there are important critiques that have been made both more widely and specifically for what archaeology has come to take more seriously since both processualism and early structural studies in archaeology. First, and not surprisingly, as noted above, it was the ahistoricity of much structural analysis that bothered many an archaeologist, and this lack of history and concomitant engagement with change is part of what might be noted as a false contextuality of structuralism. At its most extreme, underlying structures are represented as almost frozen and as static. As such, there is little space or place for the actions of humans; "they play the games but they can't change the rules." That is, many structural analyses sidestep (or ignore) the fact of practical action and the intentions of social actors (which has been a similar critique of the systems approaches of processual archaeology). In fact, the individual subject is "decentered" and the new subject tends to become the system itself (after Eagleton 1983: 112–3).

This concern is also manifest in the usually formalist analyses of structural approaches. As noted (Conkey 1989: 139), the structuralist method, in general, brackets off content and focuses more on forms; it is the structure of relations that is scrutinized. The method, furthermore, is said to be "quite indifferent" to the cultural value of (what might be called) "the text": it is an analytical not evaluative method (Eagleton 1983: 96). While some of the archaeological applications of structural assumptions and premises have attempted to address this and other weaknesses (see in Hodder 1982b; Hodder 1986) in some of the pioneering applications of structuralism to archaeological phenomena (e.g., Leroi-Gourhan 1965), there is no doubt that among the missing are individuals, intentions, and an inquiry into the *contexts* of making and using material culture (in Conkey 1989).

But this is to get ahead of the discussion and to anticipate the retrospectives of the 1980s on inquiry of the 1960s and 1970s, perspectives that view the making of art, architecture, and material culture as a practice rather than as an object. Yet, it could be argued that to take the new views might not have been possible without what can be called the "structuralist breakout." I have previously made (Conkey 1989) an observation that is neither novel nor unique, namely, that inherent in the very nature of what structuralism is predicated upon is the emergence of what became "post-structuralism" in wider theoretical circles and post-processualism in archaeology. For example, with the study of Paleolithic art, what a structuralist approach opened up was that if the images could be understood as a system of signification, as a system of meanings, then many potential significations were possible. Specific to the studies of Paleolithic art that had previously been dominated by single, all-encompassing "explanations" (such as that the art was "art for art's sake" or it was "hunting magic") was the opening up of the imagery to multiple approaches: the art as a way to solve socio-spatial relationships, as a way to mark time and seasons, and as a way to establish and maintain alliances, among others. Thus, it was then possible to suggest that what we have lumped under one broad category of "Paleolithic art" may well be not just one, but several – and possibly interpenetrating – sign systems.

The wall art of caves – among many other domains of archaeological inquiry – was not something out of scope or reach of a scientific archaeology because now it could be studied systematically and even quantitatively and it put such a previously marginal archaeological phenomenon into a conceptual framework for archaeology that could seriously engage with the cognitive and the symbolic aspects of the human mind. Structural analysis of these images (as with structural analyses of other materials and objects) displaced the question of meaning from the individual boundaries of particular images ("what does this painted horse mean?") to the relationship (s) among the images and their placements within the cave. One could also displace the question of meaning in a different direction, from the individual boundaries of objects, images, and forms to the productive contexts within which the imagery or whatever had become invested with meaning. This displacement anticipated the subsequent concern and focus with the very contexts – and practices, including those of individual agents – that more traditional structural analysis had left out. A "structural breakout" led to more interest not with the structuralism, but with a structural analysis that could begin to make sense of how and why the structures "made sense" in particular historical contexts of social action. To understand the "intentions" that most classic structuralist studies did not really ask about was however another redirection of inquiry. While not inquiring into "intentions" in the sense of getting into the mind of the maker(s), a structural approach could be interested in the intentions of a cultural product so as to "interpret it as being in some sense oriented, structured to achieve certain effects" (Eagleton 1983: 114).

Key Issues

Under the rubric of what constitutes a "structural approach" in archaeology, one can see how many of the goals and perspectives of various different theoretical perspectives can be attempted. Much

of the "early" structuralism of the 1970s was congruent with the processual assumptions that understood culture to be an adaptation and to have been systemically organized, including in terms of not just energy and matter but also information. Thus, several studies showed how certain underlying structural patterns – of architecture, material culture – could have been "adaptive" and solutions that contributed to the maintenance of cultural systems. Others suggested that the structures were crucial to the production and continuation of key information, information that was manifest by a kind of resonance among multiple levels at which a structure was operating, from how one arranges people and objects in the local arena to how overarching systems of relationships between polities were played out.

To some extent, the kind of cultural world views that were embedded in and manifest by the architecture of houses and by the kinds of serving dishes used – as expounded by Deetz for colonial America – was structural premises that integrated within and yet differentiated between cultural systems. And above all, one might suggest, despite the objection some might raise about how processual archaeologies were not about the "recovery of mind," the structural studies were simultaneously providing a framework whereby the place of the human mind in constructing meaningful worlds could be within archaeological inquiry. Thus, it is readily argued that one key contribution from earlier structural archaeologies is that material culture – a key focus of archaeological research and inquiry – was now understood to be meaningfully constituted and that it is formed and ordered by systems of meaning. Further, it conveyed the important idea that categorization and classification organize the social construction(s) of reality. These understandings are, in many ways, integral to some fundamentals of what was to become a post-processual archaeology and the current focus on cognitive archaeology and materiality (Renfrew 1994; Abramiuk 2012).

One current issue is the reexamination of the relationship between Structuralism and the field of semiotics (Conkey 2001; Layton 2006), which simply can be called the "science of signs." Interestingly, in his first version of summarizing and evaluating structural approaches in archaeology (Hodder 1986), Hodder addresses only structural approaches, but by the 3rd edition (Hodder and Hutson 2003), the chapter has expanded to "Structuralist, post-structuralist and semiotic archaeologies." Simplistically, semiotics uses structuralist methods, which treat cultural phenomena that may not be thought of as a system of signs as if it were one. As one of the premier scholars responsible for the formation and elaboration of semiotics, Saussure (a Swiss linguist) has noted: "A science that studies the life of signs within a society is conceivable. . . I shall call it *semiology*" (Saussure 1959: 16). On the one hand, Saussure understandably developed his ideas in terms of language, recognizing that the linguistic sign has two components: the *signified* or idea and the *signifier* or the spoken sound(s) that conventionally express that idea. On the other hand, he already saw that "there were many other sign systems in human culture that could be studied using the same methods" (Layton 2006: 30).

To use again the example of Paleolithic cave art, a structuralist-semiotic approach meant that one could treat the imagery as a system of signs, and thus attempts at reading the *signification* of the imagery in and on the rock were possible. But as has been noted by many (e.g., Hodder and Hutson 2003: 59–65; Preucel 2006), there are substantively important limitations to the Saussurean semiotics for the study of the material and visual worlds of archaeology, such as the "focus on codes and rules at the expense of social practice" (Preucel 2006: 3). It is a much longer story to discuss the subsequent development of semiotics and how the work of Charles S. Peirce went in important new and different directions that have been shown to have much more viable applications in archaeology (e.g., Preucel 2006). In many ways, semiotic or semiotic-inspired archaeologies are more explicit and more visible on the landscape of contemporary archaeology than are structural ones, which makes for an interesting analysis of why this might be the case.

Another issue is the emerging engagements with theories of practice. Nowhere is this better seen than in the archaeological inquiry regarding

gender. This inquiry more fully emerged in the later 1980s and is usually considered as one dimension of the post-processual archaeologies. As with most feminist-inspired theory and research, the trajectory of understanding and studying gender for archaeology has been an evolving one, although one cannot neatly categorize engendered archaeology into subsequent "waves" or even schools. To many, taking on gender has long been a simple expansion of the variables to look at, along with status, class, and ethnic groups, a version of just adding, in this case, gender, with little or no theoretical or methodological ruptures. Often, gender was taken on primarily as yet another structure, as a set of underlying principles or rules about what men do, what women do and how the division of labor was to be organized, and how this, in turn, structured activities and social status. Yet some of the very same critiques of structural assumptions and approaches could be applied to the investigation of gender as structure. In fact, related developments in feminist theory can be said, in their own concerns, to have converged with the critiques of structural approaches as "missing" the social actions, the agency, the practices, and performances of social life. Although classical "practice theory" cannot be heralded for its engagement with gender, performance theory and performing gender (e.g. Butler 1990) were important inspirations for conceptualizing the workings of gender that went beyond the gender-as-structure and gender-as-structuring approaches, even if some of those were crucial to getting gender on the table as a viable topic for archaeological research.

Future Directions

One of the strongest arguments for what a structural approach can do – and does do – for archaeology was that of Wylie (1982), who advocates that there are various "compelling reasons why archaeologists should adopt some form of structuralist approach" (1982: 39). If you are interested to "the epistemological questions that a structural archaeology raises about the kind of scientific or other knowledge that archaeologists should be striving to realize," you will find in this chapter a still-valid and important discussion. She notes how structural analyses (even those only up to 1980) have opened up domains of not just inquiry but insight and why structural archaeology need not be set aside or dismissed because "its theories are empirically under-determined" (1982: 39). Writing this, on the cusp of what would become post-processual approaches in archaeology, Wylie concludes that the "great value" of a structural archaeology is that archaeologists are now face to face with having to engage with "the cognitive, semiological and symbolic significance of their data as distinctively cultural materials" (1982: 46) and, not insignificantly, of having to figure out methodological ways to do this that, in her view, would help move the discipline of archaeology "decisively beyond" the kind of skepticism and even narrow empiricism that had not just controlled but compromised the potential of archaeological understandings.

Yet some 24 years after the Wylie chapter, Layton notes that archaeology (still) needs to "develop systematic procedures for assessing reconstructions of meanings from past cultures" (Layton 2006: 40). Even though the practice of focusing on dualisms and polarities has been displaced, the critique of Gellner (1982: 123) that the description of the structures is not the same as an explanation of how they came about and were generated may still plague some, but not all, approaches in archaeology that are inspired by structuralisms. At a wider level of inquiry, there has been much debate and discussion about the legacy of the concept of "text" that derives from the early structuralist approaches (and their roots in linguistic theories). As one core concept in the debates and discussion that emerged under the label of "post-structuralism," archaeologists have variously engaged with the relative utility and limitations of the idea that we can "read" the materials of the archaeological record and their relationships "as text" (see in Preucel 2006: 135–46). One legacy of structuralism has been that it often provided an account that was essentializing and totalizing, as in characterizing an entire past culture in terms of a generative underlying structure that itself structured cultural

practices. Within-group variations in the construction and reception of meaning(s) were suppressed, along with the already-mentioned features of much original structuralism, namely, history, agency, and the contingency of meaning making.

Yet many of the assumptions and especially the goals of structuralist approaches in archaeology not only did provide the new insights that Wylie was heralding, but also they fused into a variety of approaches that many may see as separate from structuralist ones. Preucel (2006: 120–1) has been especially concerned to note the various seemingly different archaeological programs that have been influenced, if not in part spawned, by a structural archaeology. While partially congruent with many tenets of processual archaeology and, in fact, actually contributors to the formation of processualisms, structural archaeologies also brought an array of new perspectives and insightful other ways of framing archaeological inquiry: information exchange, structural Marxism, World Systems Theory, cognitive archaeology, and even gender. With some of these allied approaches, as with structural ones themselves, there is an inherent critique of the assumptions and an emergence of critiques that move the research framework to another domain (as in the conception of ideology by structural Marxists that becomes a critique of processual archaeology).

And thus, we can return to an opening point of this summary, namely, that not only have the influence and scope of structural approaches in archaeology been underappreciated but in such initial structural approaches have been the seeds of new and more expansive ways of understanding the past. As such, in the very approaches under the rubric of structuralism in archaeology exist the critiques and a generation of the "beyond structuralism" and, along with it, a "beyond processualism." There continues today a structural archaeology in new forms and with new lines of inquiry.

Style: Its Role in the Archaeology of Art

Inés Domingo Sanz[1] and Dánae Fiore[2]

Introduction

The Relevance of the Concept of Style in the Archaeology of Art

Style has been and still is a core concept in the field of the archaeology of art for several reasons, including the fact that it is a twofold term: on the one hand, it refers to a quality of past human

actions which is perceptible in material culture, and on the other hand, it is also an analytical tool that allows archaeologists to find continuities and discontinuities in the archaeological record which are relevant to answering questions about the spatial and temporal distribution and qualities of cultural practices.

The concept of style is particularly relevant to the archaeology of art because, among other material culture products, the creation of artworks (be them artifacts or structures) entails the manipulation of form, color, size, texture, volume, etc. in the creation process, which often show recurrent patterns that evidence the underlying operation of stylistic rules and habits. Thus, style studies tackle numerous aspects of image making and display, including the trends underneath the design of visual motifs, their combinations and layout, the techniques used in their production, as well as the types of objects and contexts in which such images were created and displayed, the functions that they had for their creators, and the effects they generated over their users-viewers (Conkey and Hastorf 1990).

Yet, style has also been an analytical tool used by archaeologists to pinpoint visual similarities between artworks, in order to map their spatial distribution and/or to create stylistic sequences. In turn, these have often been interpreted as evidence of underlying archaeological cultures, which produced such similar traits, although such interpretations have also been challenged and much debated in the last 30 years (Conkey and Hastorf 1990). Such theoretical approaches and debates are reviewed in this entry.

Definition

What Is Style in the Archaeology of Art

Many archaeological research projects on art materials (rock art, portable art, pottery decoration, sculptures, friezes, etc.) have relied heavily on the concept of style, as a tool to classify artistic assemblages, create evolutionary sequences, and explore the distribution of specific artistic traditions in order to discern past identities. Although commonly understood as a way of doing, particular to a specific time and place, this concept has been defined from different and sometimes conflicting theoretical frameworks (Conkey and Hastorf 1990). Some key elements are explicitly or implicitly common to most definitions of the term *style*, which is recognizable when *comparing* a sample of *archaeological images* which show *shared features*, including (a) a common *repertoire of motifs*, e.g., their form, color, and size; (b) a common way of *displaying such motifs* on the media on which they are laid out (ceramic vessel, bedrock, bone artifact, etc.), e.g., their position, orientation, symmetric arrangement, and use of media features (its concavity/convexity/flatness, volume, topography); and (c) a common set of *image-making techniques* (including raw materials, tools, and technical operations to use them). Other features, such as the contexts in which these artifacts or structures were produced and used, as well as the functions and effects they had on their creators and viewers, do not appear in every definition of "style" and are more dependent on each theoretical approach to this concept (see below).

Historical Background

Style from a Normative Culture-History Framework

The first formal use of the concept of style in archaeology and thus in the archaeology of art was developed by the culture-history framework: it conceived style as a set of mental rules that operated within a broader set of cultural norms and which were projected into the creation of images with certain recurrent features that were recognizable in the archaeological record: types of decorative motifs, color choices, artifact shapes, depicted themes, decorative techniques, etc. (e.g., Breuil 1952; Leroi-Gourhan 1968). Hence, style became a diagnostic trait by which archaeologists identified/created "archaeological cultures." Thus, styles' spatial distribution became key indicators of the diffusion of cultural norms from one site or region to another, while stylistic sequences formed by the diachronic succession of styles became the backbone of archaeological

periodifications. In turn, styles became chronological indicators for relative dating, motif types, and forms being used in some cases as "fossil guides" to date artworks.

The shortcomings of such theoretical framework are many and have been clearly pinpointed by several authors (see their contributions below). Firstly, these normative approaches to style clearly saw it as a reflection of a mental set of shared rules and, as such, as a passive factor in human life: persons were seen more as the passive "bearers" of style rather than as its producers and manipulators. Secondly, style was mainly separated from function insofar as it was regarded more as the result of repeated norms than as the result of a social practice with certain practical purposes. Thirdly, this perspective was clearly homeostatic since its emphasis on the *shared* rules disregarded the possibility of manipulations, impositions, negotiations, and/or contradictions within the people who produced, circulated, and consumed specific style-bearing artifacts and structures. These issues where to be tackled by the following theoretical approaches.

Style from a Processual Framework

The deep breakthrough generated by the processual framework in archaeology through its explicit and thorough criticism towards culture-history did have a clear effect on the way style was conceived in art analyses. The pioneer work by Binford (1965) led to two key new ideas about culture, which was now conceived: (1) as "a system composed of subsystems" (Binford 1965: 203) in which "different classes of archaeological remains reflect different subsystems" (Binford 1965: 203) and (2) as "man's extrasomatic means of adaptation (White 1959: 8)" to the environment (Binford 1965: 205). This meant that "people, things, and places are components in a field that consists of environmental and sociocultural subsystems, and the locus of cultural process is in the dynamic articulations of these subsystems" (Binford 1965: 205). Thus, culture "is not necessarily shared; it is participated in by men" (Binford 1965: 205). Such ideas had a deep impact on the way style was conceived by processual archaeologists: culture – and style within it – was not just in people's minds, was not necessarily shared, and was not detached from the environment: culture involved practice and had adaptive functions to the environment. Did style have functions too? The answers to this question had a broad variety of replies within the processual framework.

Binford himself proposed that stylistic variability could be defined as the continuity of "formal attributes, which vary with the social context of manufacture exclusive of the variability of the use of the item" (Binford 1965: 208); that is, style and use (or function) of an item were seen as separate but interrelated realms. To pursue their study, he devised a complex set of interrelated variables to be approached through a multivariate perspective:

(a) *Formal variation* was seen as integrated by morphological variation and decorative variation, which in turn were intersected by the technical dimension and the design dimension (Binford 1965: 205).
(b) *Cultural variation* was conceived as integrated by four variables: techno-morphological, morphological design, decorative techniques, and decorative designs, which, in turn, were intersected by the primary functional variation (directly related to the specific use of an artifact) and the secondary functional variation (a by-product of the social context of production and use of the artifact) (Binford 1965: 206). This multivariate approach was foundational in the analytical separation between style and function, which was later reelaborated by other authors.

Sackett (1977) also made a clear distinction between the style and function operating in three scales: entire archaeological assemblages, artifacts, and attributes that characterize them (1977: 371–372). Yet he did remark that both were contrasting and complementary features. Function was conceived as a feature perceived in the actions, ends, and roles that an artifact performed within its context, while style was conceived as the choices made by a society within a broad range of equally valid alternate

means of achieving the same end (i.e., the same artifact) (1977: 371–372). Such choices were socially transmitted and thus had diagnostic value in the archaeological identification of cultural traditions and of the degree of intensity of social interaction between two historically related loci (1977: 371–372).

Breaking away from the processual framework and proposing a neoevolutionist approach, Dunnell (1978) focused on the concept of natural selection as a key to addressing evolutionary processes underlying cultural change. In doing so, and contradicting the processual approach, he noted that "a substantial segment of the archaeological record is not best understood in terms of adaptation" (Dunnell 1978: 192), because stylistic features of material culture were not adaptive. Thus, he proposed that there existed a fundamental dichotomy between function – accountable in terms of evolutionary processes – and style, accountable in terms of stochastic processes, that is, not subject to the bias of natural selection (Dunnell 1978: 192). These concepts have been challenged as well as revisited and refined (e.g., Hurt and Rakita 2001; Shennan and Wilkinson 2001).

Following Dunnell, Meltzer restricts the term style to refer to "those forms in a cultural system that do not have detectable value: those forms are adaptively 'neutral'" (Meltzer 1981: 314). Style, as a residual attribute, is interpreted as added for purely social purposes. On the contrary, functional features do not depend directly on transmission factors or interaction between groups but may result from adaptations or the development of similar activities in similar environments.

Contrary to these views, a number of researchers have suggested the coexistence of different styles with different functions within the same culture, with differences between religious and secular art, or between civil and domestic art (Schapiro 1952: 294). Similarly, Smith observes the use of two different styles among the Aboriginal people from Barunga (Arnhem Land, Australia) with different functions: a figurative style for non-ceremonial contexts and a geometric style for ceremonial contexts (Smith 1994: 241).

A different approach to style was developed by Wobst, who defined it as "that part of the formal variability in material culture that can be related to the participation of artifacts in processes of information exchange" (Wobst 1977: 321). The author broke the style/function opposition and proposed instead that "stylistic behaviour does have functions" (Wobst 1977: 321). Following core concepts of communication theory, Wobst viewed artifact styles as media through which messages could be encoded by emitters even in the absence of receivers, while, in turn, messages could later be decoded in the absence of emitters. The longevity of artifacts (though clearly some are highly perishable) and the control of the emission of messages via the use of rare materials or high-cost energy investment in the signals were conceived as particular features of this mode of information communication. He also pointed out that the archaeological expectations of stylistic behavior include:

(a) Artifacts with high visibility.
(b) Artifacts which are "potentially encountered by more individuals" and most accessible to them.
(c) "social-group-specific stylistic form[s] should occur only among those messages that are most widely broadcast, that broadcast group affiliation, and that enter into processes of boundary maintenance" (Wobst 1977: 330).

Yet social interaction interpretations done by other authors were severely challenged by Plog (1978), who pinpointed numerous false assumptions underlying several stylistic ceramic studies (e.g., that "all households made the pottery they used" and that "manufacture of ceramics was a female activity") and thus proposed that "one should not simply calculate a similarity coefficient between design frequencies at two sites and assume that it measures interaction and nothing else" (Plog 1978: 368). Following the work of Wobst (1977), Plog (1978), and others, in the 1980s several authors addressed style as a process of social interaction and exchange, both in the analysis of portable art (e.g., Gamble 1982) and

rock art (e.g., Jochim 1983; Schaafsma 1985; Smith 1992a, b, 1994).

Style from Post-processual and Social Frameworks

The post-processual and social frameworks challenged several of the ideas about style mentioned above: they share in common the fact that they see style as an active factor in the production and manipulation of material culture, a factor that stems from human agency, can be used as a source of power to do things and over people and resources, and thus, having crucial effects on the social lives of those involved in the creation, circulation, and display of artifacts and structures fashioned with a particular style, operating within a particular context. However, as will be noted below, these approaches do strongly differ in their epistemology: those labeled here as "social" being more prone to neopositivist and dialectical epistemologies combining induction and deduction, while the post-processual ones being more prone to hermeneutic and interpretive epistemologies.

As a pioneer of post-processual archaeology, Hodder contested the adaptationist and functionalist notions of culture and style and proposed that material culture was better conceived as "the environment within which individuals find their places and learn the places of others, their goals and expectations. Yet it also produces new situations and is . . . the medium through which individuals achieve their ends" (Hodder 1985: 5). Thus, as part of any material culture item, style involved social action, including simultaneously "meaning and experience, subject and object, interpretation and observation" (Hodder 1985: 4). Moreover, the political dimension of style was stressed by pointing out that pottery decoration, for example, could be interpreted as "part of the negotiation of power, defining boundaries, and producing social differences" (Hodder 1985: 4). Many of these ideas are still in use.

From a more social and ethnographic point of view, Wiessner (1983, 1989) defined two key concepts related to the links between style and identity that have generated an important debate in archaeology: emblemic style was defined as the formal variation that consciously transmits information about affiliation to a group, while assertive style was defined as the formal variation that carries information about individual identity. While this distinction is extremely meaningful in terms of the multiple social implications of style as an identity marker, it also has some shortcomings when applied to certain prehistoric archaeological contexts in which the distinction between assertive or emblemic becomes untestable.

A similar set of concepts was devised by Macdonald (1990), who stated that protocol referred to the set of steps undergone in the production of an item within a stylistic framework, while panache referred to the ability of an individual to negotiate and push the boundaries of such protocol for his/her own aims.

In turn, Sackett (1990) elaborated his previous ideas about style and function and proposed a set of concepts: *isochrestic variation* was related to the choices made between variants that are functionally equivalent and transmitted neither intentionally nor consciously through enculturation within social groups, but rather passively and inadvertently (hence, challenging Wiessner's notion of an emblemic style consciously informing about identity); *iconological variation* was related to the active and intentional communication of contents through the creation and selection of specific images and/or designs. Thus, Sackett had proposed a more complex dichotomy:

(i) passive style = isochrestic variation = function

versus

(ii) active style = iconological variation = communication

To this, Wiessner (1989) replied that both aspects of style – functional and communicative – could be passive and/or active, hence breaking such strict dichotomy.

Finally, from a more openly social and materialist theoretical point of view, Earle has analyzed the manipulative uses of style as a justification of

social inequality (Earle 1990). The author has pointed out that, among other factors, artifacts and structures created using elaborated art styles, luxury items, and durable materials generate aesthetic, and affective reactions can be very effective means of conferring individual's roles, status, and power due to the fact that they look not just visually appealing but also solid, permanent, and thus unquestionable (Earle 1990).

Key Issues/Current Debates

Current Uses of the Concepts of Style: Key Elements in Style Analysis

In the twenty-first century, style still plays a significant role as a tool to discern social identities and to establish relative chronologies when analyzing art materials and more particularly rock art. While portable forms of art can be dated through the archaeological context where they are found, direct rock art dating is still problematic, and when possible, it generally dates a particular motif or artwork. But an absolute date would only be meaningful to the archaeological study of art if the motif or the artwork can be assigned to a specific stylistic assemblage or unit defined by the reproduction of a certain set of common principles. Only then will we be able to identify artistic traditions, assign them to specific time periods, and explore their geographic distribution, to study the duration and intensity of specific occupations, the boundaries and interactions of specific human groups, and other aspects related with human geography and exchange networks and their evolution over time (Domingo 2005, 2012).

In order to obtain information about the past through the analysis of artworks, we need to systematically describe and quantify their main characteristics and compare them, looking for similarities and differences to classify them in meaningful units.

But what are the key elements in style analysis?

Style, or the particular way of doing of a specific individual or group, can be found in any step of the process of production (Leroi-Gourhan's 1964 notion of *Chaine Operatoire*), of an artwork, whether technological, formal, or functional. When producing an artwork, there is a range of choices from which the artist can select, either intentionally or simply by following a set of instructions learned in a specific context. The artists' choices can be unique to them or their group, and thus they become stylistic.

To find traces of identity through the analysis of artworks, it is necessary to systematically decompose their process of production, since stylistic behavior can be identified in different steps of this process:

1. Style can be identified in the formal features of an artwork (form and decoration). The study of the formal features is usually approached through visual analysis, including systematic description of different descriptive categories (always adapted to the type of artwork under analysis, whether rock art, portable art, body art, and so forth) and quantification of their frequency to observe if they change over time and/or space. Some of these categories include:
   (a) Motif types (abstract, geometric, or figurative and their subcategories, such as humans, animals, plants, and objects).
   (b) Shape (proportions, modelling, animation, perspective, and so forth).
   (c) Size.
   (d) Formal relations in space (patterns of composition and scenes). Once motifs have been analyzed, it is important to look for regularities in the way they are distributed through the panel or artifact, in order to discover if different rules of composition and arrangement exist. Similarly, compositions and scenes have to be carefully analyzed looking for changes in subject matter.
   (e) Patterns of addition and superimposition. The way the motifs are added to the panels or artifacts can also be specific to a particular individual or group. Do they use specific areas of the panel or artifact? Do they use new sites or surfaces, or do they reuse previously used ones? Do they respect previous motifs or overlap them? How is the morphology of the decorated

surface integrated in the composition or scene? Superimpositions of motifs that are stylistically similar may simply be an artistic license to show group perspective. But those including different styles are quite significant for stylistic analysis since they offer a sequence of events, and thus, they are useful to establish relative sequences.

(f) Analysis of the spatial distribution in the natural and cultural context. The distribution of portable art may provide information on the geography of specific traditions but also on exchange networks. But rock art is fixed to place, and thus it is a relevant source of data to understand the way space was defined and used by a specific group, the duration and intensity of the occupation, and how the perception of a specific place changed over time in the construction of social identities (Lenssen-Erz 2008; Domingo et al. 2008). When talking about rock art, this is usually explored through landscape analysis.

2. Technological features (medium and production techniques).The way the artworks are made can also be stylistic. From raw materials and resources to produce binders, paintings, and tools, to the selection and preparation of the decorative surface (rock or portable art), the selection of the techniques (paintings, engravings, or carvings), and so forth may all be constraint by cultural practices. While some aspects of the technological process of production can be explored through visual analysis (selection of canvas, preliminary preparation of the working surface, decoration techniques), others need to be explored through archaeometry (like pigment analysis) or experimentation (like analysis of gestures, potential tools, and so on). Interestingly, as suggested by Gosselain (1992: 90), while the visual aspects of an artwork can be easily replicated by different cultures, non-visual aspects, such as pigment recipes, are more difficult to reproduce and thus provide the opportunity to explore the more stable aspects of social identities. As an example, Groenen suggests that the identification of different painting recipes and different application techniques in the analysis of the hand stencils from Gargas results from different artistic events, in contrast to the single intervention deduced by Leroi-Gourhan through formal analysis (Groenen 2000: 60).
3. Function. When talking about function, we refer to both the utilitarian function (related to the material use of an object) and the non-utilitarian function (related to social, ideological, or spiritual spheres) (Sackett 1977: 370). The same human group can potentially use different styles for different functions, and thus, two different styles do not necessarily refer to two different periods or cultures. Here, the analysis of the context would be central.

To summarize, any integral stylistic study should combine formal, functional, and technological analysis, in order to achieve a more objective approach to style, trying to define different social units and to determine their limits in space and time (Domingo 2012).

Future Directions

The Archaeology of Style in Art Materials

A review of the concept of style and its use in the archaeological study of art confirms its value as a tool to explore past social identities and to construct relative chronologies of different sorts of artworks. Together with the systematic description, quantification, and classification of the artworks, future stylistic studies would certainly need to be complemented with more accurate absolute dates (especially in rock art) to provide a more precise chronological control of the art traditions; more accurate recording methods, in terms of the images, their spatial setting (landscape, topography, bedrock in rock art, or other materials in portable art), and production techniques; and, finally, controlled uses of ethnographic and historical resources as sources of hypotheses or as analytical tools to search for stylistic trends.

Su Bingqi

Raphael Wong
University of Oxford, Oxford, UK

Basic Biographical Information

Su Bingqi 蘇秉琦 (1908–1997) was born in Gaoyang County, Hebei province, China, in 1908 (Wang 1997; Falkenhausen 1999). He studied history at Beiping Normal University from 1928 to 1934 before joining the archaeological team of the Society of Historical Studies (after 1936, the Institute) of the National Beiping Academy and excavating the Doujitai site in Baoji, Shaanxi province. After the establishment of the People's Republic of China in 1949, Su was employed as a research fellow at the Institute of Archaeology under the Chinese Academy of Sciences, and later, the Chinese Academy of Social Sciences. In 1952, he was appointed professor in the history department of Peking University, where he founded, and served as chair of, China's first archaeology program. He was elected president of the Association for Chinese Archaeology in 1986, succeeding the former director Xia Nai (1910–1985).

Major Accomplishments

Su had a profound influence on modern Chinese archaeology (Wang 1997; Yu 2001; Hein 2016). He popularized the typological method refined by Swedish archaeologist Oscar Montelius (1834–1921). By using this method, which arranges materials in developmental sequences based on changes in forms, Su developed a chronological sequence of pottery *li*-tripods found at Doujitai. He also demonstrated that the Banpo and Majiayao cultural types were two contemporaneous branches of the Yangshao culture, instead of two sequential branches as generally thought. His chronology of the late Zhou tombs at Luoyang, Henan province, has long served as an important source for relative chronologies (Falkenhausen 1999).

Su's multiregional model for Neolithic and early Bronze Age cultures has shaped current archaeological thoughts in China. He suggested that there were six major cultural regions: the northern region centering on the Great Wall; the eastern region centering on Shandong province; the central plain adjoining part of Shaanxi, Shanxi, and Henan provinces; the southeast region centering on Taihu Lake; the southwestern region centering on Dongting Lake and the Sichuan Basin; and, finally, the southern region including Poyang Lake and the Pearl River Delta as its axis. He argued that these cultural regions had its own origin and developmental trajectory, and each interacted constantly with the others. This regionalist model challenged the conventional view that Chinese civilization originated and diffused from the area along the Middle Yellow River Valley, and it has found wide acceptance in recent years.

Su also advanced the theoretical foundation of the field by formulating the "Three Stages" and "Three Models" theories. He suggested that Chinese civilization evolved from "early cultures" (*guwenhau* 古文化), to "early cities" (*gucheng* 古城), to "early states" (*guguo* 古國). Early states were the first stage of a three-stage development hierarchy and were followed by "regional states" (*fangguo* 方國) and "empires" (*diguo* 帝國), represented by the Hongshan culture, Lower Xiajiadian culture, and Qin empire, respectively. He also proposed the "Three Models" theory that synthesized the dynamics of state formation. The "Original Model" applied to early and regional states in the northern region that emerged as a result of labor division and social differentiation. He argued that Hongshan was the earliest manifestation of a complex social organization; thus, it marked the "dawn of Chinese civilization." The "Secondary Model" denoted states in the central plain, including the archaic states of Yao, Shun, Xia, Shang, Zhou, and Qin that emerged from interactions between influences from other regions

and divisions of labor for water control projects. The "Extended Model" applied to states formed by steppe peoples, such as the Xianbei, Khitan, and Manchu, through influences from China. According to Su, Chinese civilization was the result of "divisions," "clashes," and "integrations" of different cultures.

Su also contributed by setting a clear direction for the development of the field of archaeology. He proposed to establish a Chinese school of archaeology with the aim of reconstructing Chinese prehistory through collaboration between archaeology, history, and anthropology. He also advocated the integration of Chinese and world archaeology, in order to advance the understanding of the histories of both sides. His regionalist model categorized the six cultural areas (see above) into two clusters, which emphasized their connections with either the continents or the oceans. He drew attention to people living in periphery areas and their role in creating a bridge between China and the outside world, which has become a heated research subject in current Chinese archaeology.

Su is praised for his contribution to the popularization of archaeology. Not only was he involved in the production of archaeological documentaries broadcast by China Central Television, his final book, *New Investigation of the Rise of Chinese Civilization* (Zhongguo wenming qiyuan xintan 中國文明起源新探), later translated into Japanese, was published with a primary goal of addressing both scholars and the general audience.

Submerged Indigenous Sites

Amanda M. Evans
Tesla Offshore, LLC, Prairieville, LA, USA

Introduction

Land-based archaeological sites may be inundated through a variety of processes, resulting in submerged and potentially buried evidence of past human behavior. Submerged environments create unique conditions of archaeological preservation, especially for fragile materials such as textiles. In some cases, submerged sites on continental shelves or lake shores that were formerly exposed as dry land may represent evidence that predates the terrestrial archaeological record for that same area. Submerged indigenous sites are particularly informative in studies of human migration and patterns of early colonization and occupation but can be challenging to locate.

S

Definition

A submerged indigenous site is defined as a spatially defined accumulation of cultural material or anthropogenically altered ecofacts, of sufficient quality and quantity to allow for inferences about past human behavior at that location, that through eustatic (changes in water volume) or isostatic (changes in crustal plate elevation caused by sediment loading, or tectonic rebound) processes or intentional inundation are presently located below water.

Historical Background

In the United States, some branches of the federal government have required systematic surveys for the identification of submerged indigenous sites on the outer continental shelf since 1973. In order to develop accurate survey guidelines and assessment requirements, the U.S. Department of the Interior's National Park Service (NPS) funded a study to determine the archaeological potential of the Gulf of Mexico (GOM) continental shelf for both historic resources and submerged indigenous sites (Coastal Environmentals, Inc. [CEI] 1977). The goals of the study included development of a predictive model for the identification of the most likely resources to be found in an open marine environment, and the highest probability areas for the occurrence of these resources. The methodology outlined by the authors is one early example of research specific to submerged indigenous sites, and their recommendations still serve as the basis for methodologies used in modern studies.

According to the study's authors, submerged indigenous sites do not occur randomly, and the authors argued that correlations exist between specific landform types and artifacts or other evidence of past human behavior (CEI 1977: 331). The authors then made correlations between types of landforms and the effectiveness of different survey techniques in identifying these same features in submerged contexts (Table 1). The 1977 study examined landforms in environments across the entire GOM, but not all of the recommendations are applicable to all environments. The authors suggested that any investigation of submerged prehistoric resources take a three-step approach beginning with remote sensing of the area through either small-scale bathymetry or sub-bottom profiling to resolve the upper 9 m (30 ft) of sediment and acquisition of a grab or drag sample of seafloor sediments. If a probable site was indicated by the data acquired in Step 1, then subsequent data should be collected, either in the form of side scan sonar imagery of the area, bottom cores, and or additional grab or drag samples. The final step, if warranted, was recommended as underwater photography/videography, box core sampling, and or diver investigation (CEI 1977: 341). The majority of the recommendations, such as bathymetric survey or diver photography, assume that the landform or site is exposed at the seafloor, which is appropriate for environments that include sinkholes and river channels that are readily apparent on bathymetry and side scan sonar data (e.g., Gaffney and Thomson 2007). For sites or landforms that are buried by subsequent sediment accretion, these methods are insufficient; initial survey requires techniques that image the subseafloor, such as boomer systems or other sub-bottom profiler systems.

The methodologies created as a result of this study were developed specifically for landforms

Submerged Indigenous Sites, Table 1 Correlation of terrestrial landforms, cultural period, and effectiveness of survey techniques from the northwestern Gulf of Mexico

	Cultural period		Survey effectiveness	
Landform	Early archaic	Paleo-Indian	Sub-bottom profiler	Piston corer
Quarry sites	V	V	Low	Not effective
Salt dome sites	V	V	High	Medium
Spring/sinkhole sites	V	V	High	Medium
Valley margin sites	V	P	Low	Not effective – low
Natural levee sites	V	V	High	Not effective – low
Point bar sites	V	V	High	Not effective – low
Bay margin sites	V	V	Low	Not effective – low
Coastal Dune lake sites	V	V	High	Medium
Shell middens	U	U	High	Not effective

correlating with prehistoric indigenous sites in the United States. This includes highly mobile hunter gatherers of the Paleo-Indian and Archaic periods, groups that are not associated with extensive types of material culture. The predictive model included geological reconstruction and landscape change modeling, but it was recognized that few artifacts would likely exist at submerged indigenous sites on the continental shelf. Cultural signatures of human occupation were therefore identified that went beyond artifacts, such as potsherds and lithics, to include signatures more likely to be recovered in core samples, such as shells, faunal fragments, black earth, burned rock, charcoal, and pollen (CEI 1977: 172).

In the years since the creation of the submerged indigenous site prediction and preservation model used on the United States' continental shelf, subsequent studies have been conducted worldwide that add to the theory and methodology of investigating submerged indigenous sites. In 1981, in recognition of advances in paleocoastline reconstruction, archaeologists, anthropologists, geologists, and oceanographers were invited to participate in a symposium addressing Quaternary coastlines and prehistoric archaeology; the resulting papers were published in one of the first edited volumes on the subject (Masters and Flemming 1983). The participants in this symposium noted that, at that time, the majority of identified submerged indigenous sites were the result of chance finds by recreational SCUBA divers, fishermen, or activities related to offshore construction. Site discovery, they maintained, depended on both physical preservation of the site and ease of detection. The participants presented diverse case studies ranging in location from Siberia to Australia, but concluded that several methodologies could be universally applied to site prediction and detection. At the minimum, local geomorphology has to be modeled to identify areas of probable feature preservation; recognizable features (such as shell middens) must exist; and the landscape had to have offered basic requirements such as access to fresh water, protection from environmental exposure, and or availability of food (Masters and Flemming 1983: 611, 622–623). Recommendations for survey and identification of indigenous features were similar to those outlined by CEI (1977): chiefly, bathymetric or subseafloor survey conducted at tight intervals (no greater than 150 m). The authors stressed, however, that this type of survey cannot prove without doubt the existence of submerged indigenous sites, it can only identify the most probable areas in which sites could be preserved (Masters and Flemming 1983: 624).

Parallel to the Quaternary coastlines and prehistoric archaeology symposium, a follow-up study was being conducted in the United States to analyze terrestrial analogues for potential offshore deposits (Gagliano et al. 1982). The results, developed under contract for the National Park Service, analyzed core samples from verified terrestrial prehistoric sites along the northern Gulf of Mexico coast. Lab analyses of sediment core data indicated that the following variables were credible indicators of human activity and habitation: grain size, pollen content, geochemical composition, point-counts, foraminifera species identification, and radiocarbon dating of appropriate samples. Recognizing that site identification could not be dependent upon the presence of anthropogenic artifacts, the terrestrial corollaries were developed so that landscape features could be tested for indicators of indigenous site occurrence without the presence of obvious anthropogenic artifacts such as projectile points (Gagliano et al. 1982: 115).

In order to test the effectiveness of the predictive model and recommended methodology proposed by the 1977 and 1982 reports, the U.S. Department of the Interior's Minerals Management Service (MMS) funded a study in the early 1980s, concentrated in the relict Sabine River Valley on the Gulf of Mexico outer continental shelf (Pearson et al. 1986). This area was identified as ideal for testing because of a wealth of preexisting geologic data and existing subseafloor surveys conducted on behalf of oil and gas operators that were available to the researchers through the funding agency (Pearson et al. 1986: xix). Eight targeted areas were selected for inclusion in the project based on a review of existing shallow high-resolution seismic data, and then subjected to tight interval

seismic survey over the areas of interest to both relocate and further delineate the features of interest (Pearson et al. 1986: 53–76). Survey grids were located in areas where modern water depths range from approximately 8 to 16 m (27–54 ft). Vibracores were acquired from five of the surveyed areas, each measuring 12 m (40 ft) in length. The collected cores, 76 in total, were subjected to a series of laboratory analyses in efforts to identify potential signatures of anthropogenic activity, based on those identified by previous studies (Gagliano et al. 1982). No artifacts, or distinctly man-made materials, were recovered within the cores; however, two cored features included sediments exhibiting characteristics of archaeological deposits. One was interpreted as a possible shell midden, dating to approximately 8,055 +/− 90 BP and the second was interpreted as an area of burnt bone dating to approximately 8,500 BP. The study's authors were hesitant to identify the features as concrete evidence of human occupation, but stated "that they more closely resemble archaeological deposits than known natural deposits" (Pearson et al. 1986: 76–80, 127–162). The results of the Sabine River Valley study supported the theories behind the predictive model created for use in the Gulf of Mexico, and demonstrated the complicated task of identifying submerged indigenous sites from buried contexts offshore. The study area represents a unique type of submerged indigenous context in that archaeological data is not simply submerged, but also buried underneath a seafloor which gives no indication of the underlying features.

The Sabine River Valley is one example of a study to investigate submerged indigenous sites. Numerous studies have been conducted around the world, but are distinct from the Sabine River Valley study in that these other sites are either exposed at the seafloor, located in relatively shallow water depths, or some combination thereof (e.g., Johnson and Stright 1992; Browne 1994; Faught and Donoghue 1997; Momber 2000; Dix et al. 2004; Benjamin et al. 2011). Some research projects have avoided the complications of working in submerged environments by using evidence from terrestrial contexts to address changes in human subsistence and coastal settlement patterns instigated by changing climate conditions (Bailey and Parkington 1988). Estimates from the late 1990s suggested that approximately 550 submerged indigenous sites have been identified globally, dating from the Lower Paleolithic/Early Pleistocene periods, or approximately within the last 2.5 million years (Dix et al. 2004: 5).

Despite 30 years of research in locations ranging from Beringea to Argentina, the methodology used in submerged indigenous site research has remained relatively unchanged from the 1977 recommendations. As outlined by Gaffney and Thomson (2007: 4), the most common techniques used in the investigation of submerged indigenous contexts include seabed sampling and shallow coring, high-resolution 2-D seismic (sub-bottom) profiling, high-resolution 3-D seismic profiling, and high-resolution bathymetric mapping. The acquired remote sensing data or sediment samples/cores are then put into a locally specific context. These paleolandscape reconstructions remain critically dependent upon accurate understandings of sea-level, including isostatic and eustatic changes, and rates of sedimentation or erosion (Dix et al. 2004: 13–30).

Key Issues/Current Debates

The search for submerged indigenous sites is predicated on an accurate assessment of the landscape from the point in time it could have been occupied through to the present. The synchronic reconstruction of the landscape, or reconstruction of place at a given point in time, provides information about exploitable resources that would have been necessary to support populations, and discrete areas within the landscape where evidence of past occupation is most likely to be found. Diachronic reconstruction of that same place provides information about changes to the site over time that influence preservation of any archaeological materials from their time of deposition, and influence secondary site formation processes.

Sea-level change has altered the extent and shape of the world's coastlines and river-fed lakes repeatedly throughout the Pleistocene. The

landscape available to indigenous populations was expanded and minimized by these transgressions and progradations, but was also altered and reworked by these same mechanisms. Sea-level curve data is used to determine the possible time period of exposure for a given sediment horizon. Final inundation, or the most recent inundation as sea-level approached the present high-stand, marks the last possible date for potential occupation by indigenous populations as the landscape became part of a submerged environment.

Early sea-level studies were characterized by an assumption that the interconnectedness of the earth's oceans would result in uniform eustatic sea-level change, and that data from any tectonically stable region was representative of global sea-level at that point in time. It is now understood that sea-level is highly geographically and temporally dynamic. Factors that influence eustatic sea-level at any given time may include changes in ocean volume, water mass, and water density. Overall global patterns are influenced locally by relative changes associated with regional land uplift or subsidence, meteorological or atmospheric events, gravity, and eccentricity (Pirazolli 1991: 4–6).

Sea-level change can be assessed by identifying evidence of former shoreline stands and related environments, and by absolute dating of samples taken from sediment and ice. Many sea curves are created by extrapolating change between discrete data points, without regard to estimates of error (Pirazolli 1991: 21). Line graphs of age/depth below modern sea-level represent an oversimplified interpretation of sea-level change. Error ranges for individual data points allow for a more comprehensive, although more complex, visualization of sea-level change within a given data set (e.g., Balsillie and Donoghue 2004). Furthermore, oscillations and reversals become exaggerated at smaller time intervals. Positive and negative alternations of sea-level observed at a timescale on the order of a thousand years are likely to become insignificant within the overall pattern of sea-level change when viewed on a scale of tens of thousands of years (Pirazolli 1991: 21). The issue of scale becomes pertinent when sea-level curves are applied to archaeology. Sea-level curves may provide significantly different dates for a single given depth, or provide insufficient resolution for sites occupied over a span of hundreds or even thousands of years (Fig. 1).

The majority of researchers now agree that sea-level change is a locally specific phenomenon, and reconstructions must assume some measure of local variability within trends that would otherwise suggest uniform rates of global sea-level change. Factors that complicate the construction of sea-level curves include, but are not limited to, sediment compaction and local subsidence, recognition of marsh and swamp peats, water depth range of peat formation, sediment load compaction, fluid extraction, and other localized changes in conditions. Awareness of these complications has led to reevaluations of regions once considered to reflect homogenous rates of sea-level rise, and has demonstrated high rates of local variability (Lewis 2000). Archaeological studies of submerged indigenous sites must consider the applicability of sea-level curves selected for use in reconstructing the site's environment. In order to be useful in archaeological settings, rates of sea-level rise must be accurate at the site-specific level.

Technology is an important component of submerged indigenous sites research. As discussed previously, the identification of this type of site requires the use of underwater remote sensing. This is useful in lakes and coastal waters where depths exceed 1 m below sea-level (BSL); however, many sites are located in the transitional shorezone, where water depths are too shallow to allow access by boats. Archaeologists working in these environments must often use a combination of terrestrial and underwater techniques. For example, studies along coastlines often combine terrestrial pedestrian survey and probing with coring and, if possible, remote sensing. This is effective in areas where indigenous sites such as shell middens are present, but would not necessarily identify a hearth or postmold. Magnetometers, which are used to successfully identify indigenous features in terrestrial settings, are not effective in submerged contexts where water depths may not allow for acquisition of data at the intervals

Submerged Indigenous Sites, Fig. 1 Global sea-level curves demonstrate the variability within the record at different positions on the earth in the recent past. (Data recreated from Fairbanks 1989, 1990; Chappell et al. 1996; and Toscano and MacIntyre 2003)

required. The reliance on technology in submerged sites research can also make the research too expensive to conduct. Remote sensing equipment, boats, and diving equipment may escalate project budgets beyond that of a similar project conducted in a terrestrial setting.

International Perspectives

Submerged indigenous sites worldwide are beginning to receive increased attention for their potential to contribute information about early coastal populations as well as population migrations. Until recently, submerged indigenous sites research has consisted of studies of individual sites. Recent publications, particularly focusing on submerged sites in the North Sea and northern Europe, have incorporated multiple sites into regional discussions of culture at the time these now-submerged sites were occupied (e.g., Benjamin et al. 2011). Archaeologists in Europe and the United Kingdom have demonstrated the importance of data from submerged contexts. Survey requirements protecting submerged indigenous sites are also more stringent in this part of the world.

In the United States, submerged indigenous sites receive various levels of legal protection and research interest. Increasing numbers of federal and state agencies are incorporating submerged indigenous site survey and research into their management plans. In places were survey is required in order to avoid inadvertent damage to the submerged cultural resource, requirements focus on remote sensing. Particularly in the Gulf of Mexico region, where earlier studies have demonstrated the potential for submerged indigenous sites, coring is not a requirement. In most cases where a potential submerged indigenous site is identified, the responsible government agency assigns an avoidance mitigation on the target,

and no subsequent testing is required. In the United Kingdom, submerged indigenous sites are protected during offshore ground-disturbing activities such as aggregates extraction, and surveys require both remote sensing and physical samples, such as cores (Evans et al. 2009).

Future Directions

Submerged indigenous sites research is receiving increased attention in part because of climate change, and related sea-level rise. The same processes that now threaten coastal indigenous sites inundated sites in the past. Studies of submerged indigenous sites can be used to add to the archaeological record of places, but the mechanisms of inundation may also be used to protect modern sites from erosion related to modern sea-level rise.

Archaeologists must continue to investigate submerged indigenous sites. Although previous studies have focused on the methods used to locate and investigate such sites, there must be new emphasis of the context of these sites and what they mean to the local archaeological record. Sites studied in isolation are interesting anomalies. Sites discussed within the context of their spatial or temporal context provide a more complete story, and help to demonstrate the need for submerged indigenous sites research.

Submerged Prehistoric Landscapes

Joe Flatman
English Heritage, London, UK

Introduction and Definition

Submerged prehistoric landscapes are those areas of former dry land that have been submerged due to both long-term and short-term processes of environmental change, most commonly sea-level rise since the end of the Last Glacial Maximum (LGM) (c. 26,500 and 19,000–20,000 years ago) during the Late Glacial Maximum (c. 13,000–10,000 years ago) (see Mithen 2004). At the height of its extent, sea levels during the LGM were as much as 120 m lower than the present day, exposing large areas of the continental shelves of the world to human habitation. These submerged prehistoric landscapes have been known about since the late nineteenth century and scientifically analyzed since the 1970s (see, for example, UNESCO 1972; Masters and Flemming 1983). One of the most famous and early excavations of such a site is that of Tybrind Vig in Denmark, where a well-preserved Late Mesolithic (Ertebølle Culture) settlement was excavated during the late 1970s and early 1980s (see Malm 1995). Submerged prehistoric landscapes also include inland prehistoric sites in inundated freshwater environments, such as Little Salt Spring in central Florida (Clausen et al. 1979) and the submerged caves of Yucatan, Mexico (González González et al. 2008). More recently, submerged prehistoric landscape studies have tended to move away from such site-specific analyses to wider landscape analyses of the palaeogeography of the entire submerged regions (see Benjamin et al. 2011).

Alongside areas submerged as a consequence of long-term sea level rise, some submerged prehistoric sites have been submerged due to more sudden events relating to shifts in local plate tectonics, especially earthquakes and volcanic eruptions that have changed, sometimes quite dramatically, local topography (see Flemming 1971). The former, for example, are the cause of the submergence of the 5,000-year-old city of Pavlopetri that lies off the coast of southern Laconia in the Greek Peloponnese; the latter the cause of the destruction of the settlement of Akrotiri, a Bronze Age Minoan settlement on the Greek island of Santorini.

The loss of prehistoric sites either through long-term change or short-term catastrophe is thought to be the origin of many myths and legends of "lost" civilizations, most famously that of Atlantis, and more broadly of the many "inundation" stories that survive in numerous cultures' oral histories, most famously that of the Genesis flood narrative involving the tale of Noah's Ark in the Book of Genesis in the Hebrew Bible and the Christian Old Testament.

Examples

The best-understood submerged prehistoric landscapes at present are those of the European North Sea. Here, work since 1998 onwards (see Coles 1998) has analyzed with ever-increasing accuracy the range and extent of a former submerged prehistoric landscape known as "Doggerland" that used to lie between (and link) Britain with northwest Europe until flooded around 6,000 BCE (see Flemming 2004; Gaffney et al. 2009). A combination of relatively accessible sites, an extremely active marine industry focused on marine mineral extraction, and a proactive legal/management regime (especially funding provided between 2002 and 2011 by the British government under the terms of the Aggregates Levy Sustainability Fund or ALSF) all combined to provide both site-specific and broader landscape analyses for Doggerland that could be compared to relevant terrestrial datasets. The result was an unparalleled understanding of the range and significance of sites in Doggerland as well as a model for the international management of such locations. Much less well understood but arguably more famous than Doggerland is the submerged prehistoric landscape of Beringia that used to link Asia and the Americas and which functioned as the "land bridge" allowing the peopling of the Americas from c. 20,000 years ago onwards. The extreme cold and inaccessibility of this area, especially those parts of Beringia now flooded by the Bering Sea, has led to relatively limited archaeological fieldwork taking place here, although the basic extent and principle of the Beringian landmass has been known since the 1930s (see Hoffecker and Elias 2012).

Key Issues and Current Debates

The tools and techniques required to access and analyze the submerged prehistoric landscapes are now well refined and understood, and the data from such sites sits within a broader matrix of data from terrestrial prehistoric sites. As a consequence, the key issues and current debates of such sites focus most often on [a] mapping the global extent of such sites, especially in lesser-known locations and [b] agreeing the management of such landscapes, especially in relation, where present, to Indigenous Communities who may have ancestral links to the former occupants of these areas. Submerged prehistoric landscapes frequently cross modern international territorial boundaries, and as a consequence, their management is often confused (see Flatman 2012). In addition, existing domestic and international heritage management models and laws are frequently ill suited to the geographical extent and physical sensitivity of such sites. Most such heritage laws are designed to protect relatively well-preserved historic-era wreck sites that lie within a small and usually easily defined area, not characteristics common to submerged prehistoric landscapes that may cover, at an albeit low density of data, thousands or even hundreds of thousands of square miles of seabed.

Future Directions

Beyond the examples discussed above, many other submerged prehistoric landscapes are known to exist around the world, many barely explored. For example, on the basis of known sea-level changes since prehistory, large sections of the continental shelves of Central and South America, southern Africa, and the Indian Subcontinent must all have originally been dry land and were, presumably, settled by prehistoric communities. Little is known of the archaeology of such areas, although Bailey (2004) has outlined their potential. Some of the most dramatic archaeological discoveries of the twenty-first century are likely to come from such sites, where the range and extent of submerged materials may in time redraw our understanding of the date and nature of early human occupation and migration. In particular, the submerged prehistoric landscapes of Southeast Asia (commonly referred to as Sunda and Sahul – see Allen et al. 1977) may provide new dates for the earliest human occupation of Australia, potentially revising our understanding of when and precisely how that continent was occupied.

Ongoing changes in global climate leading to the warming of the Arctic and seasonal and/or permanent loss of pack ice may in particular lead to the discovery of new data for Beringia in the twenty-first century. As the Bering Straits and surrounding coastlines of Alaska, Chukotka, and Kamchatka are rendered relatively more accessible through this process, industrial developments (especially the search for oil and gas reserves) and more broadly shipping routes (especially the regular commercial use of the Northwest Passage) seem likely to lead to the discovery of significant remains from this prehistoric landscape. How such industrial impacts on these landscapes will be managed (if at all) and what part the Indigenous Communities of these areas will play in that management remains to be seen, but the worry has to be that the demands of industry will sweep concern for the past as well as present communities of such regions aside in the pursuit of short-term financial gain.

Sugarcane: Origins and Development

Tim Denham
Archaeological Science Programs, School of Archaeology and Anthropology, ANU College of Arts and Social Sciences, The Australian National University, Canberra, ACT, Australia

Basic Species Information

Sugarcane (*Saccharum officinarum L.*) is one of the world's most important crops, primarily to refine into sugar and increasingly for biofuel.

Sugarcane is cultivated for sucrose that accumulates in its stalk, although it was also traditionally grown for its edible inflorescences, for medicine, and as a raw material for weaving and a variety of other uses. Sugarcane is cultivated vegetatively by planting a stalk segment that contains a reproductively viable bud. Although widely perceived to be a traditional snack food, sugarcane has been documented as a staple in parts of the eastern highlands of New Guinea (Daniels and Daniels 1993), and its importance in other regions in the past should not be underestimated, especially for fodder (Fig. 1).

Sugarcane is an interspecific cultivar predominantly derived from the hybridization of *S. robustum* and *S. spontaneum*. The domestication of sugarcane has not been fully defined, and alternative scenarios exist (Daniels and Daniels 1993). In lieu of more intensive genetic investigations, the dominant scenario suggests initial domestication in the New Guinea region with subsequent westward dispersal and interspecific hybridization in Southeast Asia (Grivet et al. 2004).

Sugarcane: Origins and Development, Fig. 1 Bound stands of sugarcane growing in a cultivated plot in the highlands of Papua New Guinea. (Photo: Tim Denham, 1990)

Major Domestication Traits

The initial stages of sugarcane domestication have been proposed to involve the anthropic selection and domestication of a wild ancestor of *Saccharum robustum* in New Guinea (Simmonds 1976: 104–108). Lebot advanced the same scenario in his evaluation of the molecular evidence to suggest (1999: 622–623):

> … *S. robustum* is the most likely precursor of sugarcane and was domesticated in New Guinea where human selection of chewing plants with sweet juice and low fibre produced the *S. officinarum* clones. Cultivars were subsequently differentiated in numerous distinct morphotypes via vegetative propagation and selection of somatic mutants.

Lebot (1999: 623) concluded that "*S. officinarum* cultivars are derived from introgressions between wild forms of *S. robustum* and *S. spontaneum* in Melanesia." Lebot envisaged a similar domestication scenario for *Saccharum edule*, a plant cultivated in New Guinea for its aborted inflorescences.

While agreeing that initial domestication of *S. robustum* occurred in New Guinea, Grivet et al. (2004) consider that the resultant cultivar dispersed westward to Island Southeast Asia where it hybridized primarily with wild populations of *S. spontaneum* to produce *S. officinarum*, as well as with other species in various regions to produce other cultivars. Grivet et al. (2004) consider *S. spontaneum* to be a recent introduction to New Guinea.

Timing and Tracking Domestication

Archaeobotanical evidence of any antiquity for sugarcane is almost nonexistent. A putative macrobotanical find from Yuku rock shelter in the New Guinea highlands has been dated by association to 5750–4800 years ago (GX-3111B; Bulmer 1975: 31). However, the

identification of that find is uncertain (Yen 1998: 31), and its antiquity is also open to question due to disturbance at the site (author's research). A macrobotanical find from Kuk Swamp, collected from a domestic context dating to the last few hundred years, was originally identified as *Saccharum officinarum* by John Hather (Jack Golson *pers. comm*. to Tim Denham, 2012), and the veracity of this identification is still being investigated. Major problems in seeking to identify archaeobotanical samples have been the lack of reference material from other *Saccharum* species and related grasses and the current inability to differentiate *S. officinarum* phytoliths from similar grass morphotypes.

In the absence of reliable archaeobotanical identifications, an inferential method for approximating the antiquity of sugarcane cultivation and domestication comes from historical linguistics. Any derived chronological information is, however, at best tenuous. For example, a cognate term for sugarcane, namely, ∗CebuS, reconstructs to Proto-Austronesian, the languages on Taiwan before the subsequent differentiation and dispersal of Austronesian languages southward to Island Southeast Asia after c. 4500–4000 years ago (e.g., Pawley 2007). Significantly, the word for "chew on sugarcane," which is how the sugar is traditionally extracted within Island Southeast Asia and New Guinea and probably why it was originally selected by people (following Lebot 1999), only reconstructs to Proto Malayo-Polynesian (Pawley 2007); namely, the term was integrated into the Austronesian lexicon only after the languages dispersed southward to Island Southeast Asia.

It is uncertain if the linguistic reconstructions are sufficiently specific, either botanically or chronologically, to anchor an interpretation of sugarcane geodomestication. If they are reliable, then several stages in the domestication of sugarcane occurred before Austronesian language dispersal from Taiwan, including initial domestication of *S. robustum* in New Guinea, westward movement of the derived cultivar to Island Southeast Asia, and subsequent hybridization with *S. spontaneum* to form *S. officinarum*. Linguistic evidence also indicates that the practice of chewing on sugarcane to extract the sucrose-rich juice occurred in Island Southeast Asia before Austronesian languages dispersed there.

Sullivan, Sharon

Michael Pearson
Heritage Management Consultants, Canberra, ACT, Australia

Basic Biographical Information

Sharon Sullivan is an Australian archaeologist and heritage planning and management advisor and former senior public servant. She grew up in northern NSW, going to school in Glen Innes and Armidale before taking an honors degree in Prehistory, Ancient History, and Australian History at the University of New England (1964). Her honors thesis was on the Aborigines of the Richmond-Tweed River valleys. She completed a Diploma in Education (1965) and a master's degree with honors (1972) with a thesis titled *The Material Culture of the Aborigines of North Western New South Wales*, also at UNE. During her undergraduate and postgraduate studies, Sharon took part in extensive fieldwork locating, recording, and excavating Aboriginal prehistoric sites throughout NSW with Dr. Isabel McBryde and worked as her research assistant in 1966–1967.

In 1969 Sharon joined the Resources Division within the National Parks and Wildlife Service of New South Wales, where she was responsible for the location, recording, and management of Aboriginal sites throughout the state and technical advice on the acquisition and management of historic sites by the service. The success of this work led to the establishment of a dedicated Aboriginal and Historic Resources Section in 1976, which later became the Cultural Resources Section in 1983. During this period she also won a Public Service Board scholarship to study heritage site management in the USA for 3 months (1973). In 1985 Sharon was promoted to Acting Regional Director Central Region of National Parks with a staff of 320, this position being confirmed in 1986. In 1989 she became Deputy Director (Field Operations) of the NSW National Parks and Wildlife Service.

In 1985–1986 Sharon was appointed as a co-opted Commissioner of the Australian Heritage Commission, in which she coordinated a national workshop on a National Cultural Conservation Strategy. In 1990 she became the Executive Director of the Australian Heritage Commission in Canberra, subsequently promoted to Group Head of the Australian and World Heritage Group of the Australian Government's heritage and environment department. Sharon left the public service in 1999 and established Sullivan Blazejowski and Associates Heritage Consultants. Since then she has played a major role in the development of heritage management philosophy and management in Australia and internationally (particularly in relation to World Heritage management) and has run training courses in these issues in many countries.

Major Accomplishments

Sharon Sullivan's leading role in the NSW National Parks and Wildlife Service and the Australian Heritage Commission was during a period of seminal developments in the philosophy and practice of heritage identification and management in Australia. She made many significant contributions to the field, including initiation of the first agency-supported research by Aboriginal people into sites of significance in eastern Australia and developing subsequent approaches with Aboriginal people in methodology and the protection and management of Aboriginal sites. These pioneering protocols and programs in heritage management were the basis for what is taken for granted in Australian Aboriginal site management today. She played a major role in developing national systems of regional and thematic assessment of heritage and cooperative and problem-solving approaches to land-use conflicts that have been reflected in evolving legislation at state and national levels and in heritage management practice at all levels.

Sharon's expertise and heritage management skills have resulted in her appointment to many prestigious positions. She worked with the World Heritage Bureau and the World Heritage

Committee reviewing nominations, technical guidelines, and the operations of the committee as well as being for a period the Australian Government's main adviser and international representative on the World Heritage Committee. She is the Chair of the Port Arthur Historic Site Authority (a World Heritage site), Acting Commissioner in the NSW Land and Environment Court, Deputy Chair of the NSW Heritage Council, Executive Councilor of the Australian Institute of Aboriginal Studies, a member of the Australian Heritage Council, a National Committee member of Australia ICOMOS, a member of the Australian Research Council's College of Experts on the Humanities and Creative Arts Panel, and a member of the Institute for Professional Practice in Heritage and the Arts at the Australian National University. In 2001 she completed a Getty Conservation Institute Senior Residential Fellowship. She has done consulting work for the World Monuments Fund (Africa, Cambodia), World Bank (China), ICCROM (Africa), and the Getty Conservation Institute (Africa and China). Sharon was Australian project leader of the Australia-China-Getty Conservation Institute partnership in 1999–2000 to develop a set of heritage principles for Chinese site management, which were promulgated by China ICOMOS. She worked subsequently with two Chinese World Heritage sites to implement these principles. Sharon has taught and guided site managers in Australia, the USA, Cambodia, Africa, and China and is currently part of a multidisciplinary team working together with UNESCO, the Cambodian Government, and the consulting firm Godden Mackay Logan to prepare a Heritage Management Framework for the World Heritage site of Angkor.

Sharon Sullivan's contribution and standing in the heritage field has been acknowledged in many ways. She is an Adjunct Professor in the School of Natural and Rural Systems, University of Queensland; in the Department of Archaeology and Paleoanthropology, University of New England; and in the School of Anthropology, Archaeology, and Sociology, James Cook University, North Queensland. Sharon was elected a Fellow of the Australian Academy of the Humanities in 1996 and made an Officer of the Order of Australia in 2004 for her "service to cultural heritage conservation, including Indigenous heritage, and to influencing conservation practices worldwide." The prestigious Rhys Jones Medal for Outstanding Contribution to Australian Archaeology was awarded to her by the Australian Archaeological Association in 2005; Honorary Life Membership of international ICOMOS was conferred in 2005, and she was presented with an Honorary Doctorate by James Cook University in 2003 and an Honorary Doctor of Letters by University of New England in 2011.

Supermodernity and Archaeology

Alfredo González-Ruibal
Institute of Heritage Sciences (Incipit), Spanish National Research Council (CSIC), Santiago de Compostela, Spain

Introduction and Definition

The term supermodernity (*surmodernité*) was coined by French anthropologist Marc Augé in 1992 to define the period commonly known as late modernity. The usefulness of the concept of supermodernity, as compared to other definitions of the later part of modernity, rests on two things: the idea of exaggeration and the retention of the concept of modernity. Regarding the first point, Augé (2002: 26–45) talks of three excesses: factual overabundance (which is associated with an acceleration of historical time), spatial overabundance (the abolishing of distance by electronic media and transportation), and an excess of self-reflexive individuality. We can add a fourth excess: material overabundance. In relation to the idea of modernity that Augé keeps in his definition, it can be said that while some of the notions of modernity might seem to be outdated, as the defendants of postmodernity argue, its core categories are certainly not. I consider that postmodernity is, in fact, a period characterized by an awareness of the risks and flaws of being modern but which has not been able to overcome modernity's troubles. Our current concern with ecological and social catastrophe at a global scale is the demonstration that the process which started during the fifteenth century is far from finished: we are probably just witnessing its climax.

Key Issues/Current Debates

The term "supermodernity," then, captures well the essence of our present period of modern exaggeration. Another question is when to start such a period. Augé does not give clear indications, although it is implicitly understood that it covers the same time span that others identify with post-, high, late, or liquid modernity (Giddens 1991; Jameson 1991; Bauman 2000) and which begins around the end of the Second World War or later depending on the authors. This is the periodization that some researchers follow to define the archaeology of the contemporary as the study of the time that goes "after modernity" (Harrison and Schofield 2010). Although trying to parcel time may seem to be a fruitless historicist exercise, I think that it can also be a way of reflecting on history and time differently. What we need is a periodization of modernity that fits the archaeological record. It is necessary to privilege in our periodizations not the phenomena identified by sociologists, culture historians, or philosophers but the processes of creation and destruction of matter that archaeology has traditionally employed to make sense of time and change. We have to follow the time(s) of things (Olivier 2008: 247–252).

From this point of view, a moment that seems best suited to start supermodernity is the early twentieth century. It has been pointed out that the transition between the late nineteenth and the early twentieth century inaugurates a period in which globalization reaches its first apex and becomes truly global. Globalization is not just the circulation of people, images, or ideas, it is also (perhaps primarily) the circulation of material objects. This was made possible by technologies of transport and communication that abolished distance in the service of an ever-expanding global capitalism (Harvey 1990). The materiality of the world became more and more integrated – more and more similar – and the mass production of objects played an outstanding role in this process. More importantly, and perhaps not sufficiently appraised, the period that begins in 1914 is marked by mass destruction of human lives, societies, things, and the environment at an unprecedented scale in the history of humankind. Interestingly, although the relationship between globalization, production, and consumption has often been emphasized, the globalization of death has been less discussed. Thus, historians agree that the 1914–1945 period witnessed the collapse of the first globalization (Obstfeld and Taylor 2003: 125–126) as opposed to the late nineteenth century, but this is only the case if we pay attention to the movement of free citizens, capital, and consumer goods. If we look at the circulation of soldiers, refugees, war machinery, and destruction, 1914–1945 is actually a period of astonishing global integration (Fig. 1). High explosive has probably contributed as much to globalization as Coca-Cola, if not more.

Supermodernity and Archaeology, Fig. 1 Another kind of globalization: a tin can from Norway consumed by Eritrean soldiers at the service of fascist Italy in the frontier between Sudan and Ethiopia

In fact, should supermodernity end tomorrow, it would be perfectly identifiable from an archaeological point of view, thanks to global destructive processes. The things that demand the attention of intellectual gurus, social commentators, and their many followers seem somewhat banal compared to other issues that are leaving an indelible archaeological imprint in the world. In the long run, postmodern architecture would seem just like an anecdote (like the difference between Baroque and Rococo), and without new media, the pace of global integration and social change would perhaps be a little bit slower, but it would happen nonetheless. It is on the destructive operations of supermodernity that archaeology can provide a distinct and necessary critical perspective. After all, the transformations that archaeology documents more easily are changes in material organizations with high irreversibility (Lucas 2008), and these are also the ones that have further-reaching consequences historically: consider the collapse of the communist regimes, the Second World War, or the end of peasant

societies, all of which have left a wake of razed landscapes behind.

If instead of looking at destruction, we focus on creation, the situation is not different. The supermodern landscapes of creation (Penrose 2007) are also landscapes of oblivion and devastation. Urbicide is not only inflicted during wars (Coward 2008), it can also take the shape of urban renewal (Mullins 2006). In fact, destruction and construction should not be opposed; they are inextricably linked. This is obvious in slash-and-burn agriculture: the forest is felled, burnt down, and cultivated, but later the fields are fallowed and the trees revive with further strength. Similarly, the Neolithic houses of Anatolia and the Balkans were regularly destroyed only to be rebuilt again, energized by the seeds of the ancestors. The Neolithic probably marks the beginning of the strong interdependence between construction and destruction and death and the regeneration of life (Stevanovic 1997; Kuijt 2008). In this context, the destruction of houses would be "a matter of continuity rather than ending" (Hodder 2010: 150). It is not strange that this rationality emerged with the appearance of cultivation, which is also based on cycles of life and death.

Yet with modernity, this logic is no longer sustainable: unlike in Neolithic and other non-modern societies (e.g., Küchler 2002), destruction is no longer a form of continuity, regeneration, and remembrance but of rupture and forgetting. Destruction is neither a form of creating and maintaining relations but of cutting them off: death has become an end in itself. In non-modern societies, even war and predation are ways of extending relations (Harrison 1993; Fausto 1999). The change in the nature of destruction in supermodernity is no better exemplified than in the mass production of nuclear weapons that can wipe out the entire humanity: death for death's sake. Robert Oppenheimer's words epitomize the sense of a new age of total destruction: "Now, I am become Death, the destroyer of worlds." Oppenheimer's famous misquotation is meaningful: the original cite from the Bhagavad Gita is "I am become Time, the destroyer of worlds." But time can no longer destroy things with its slow rhythm as it used to. Augé (2003: 110) says that "only a catastrophe can produce today comparable effects to the slow action of time," only Hiroshima or Katrina.

Spatial Excess

One of the points that makes Marc Augé's definition appealing for archaeologists is his concern with places. According to Augé (2002), the time of supermodernity is marked by a shift from places to non-places: "If place can be defined as relational, historical and concerned with identity, a space that cannot be defined as relational, historical or concerned with identity can be defined as a non-place" (Augé 2002: 83). Non-places do not foster symbolic relationships or a shared heritage. Their purpose is only to facilitate circulation and consumption in a global world (Augé 2003: 101). Non-places have all the appearance of a dejà vu, which is not innocent: their mission is precisely to neutralize the sense of alienation in a foreign environment (Harrison and Schofield 2010: 256). They eliminate the place-ness of places. Airports, highways, malls, and hotels are typical non-places. Elsewhere, Augé (2003: 71) distinguishes between two categories: non-places of refuge and non-places of image (simulacra). The non-places of refuge are related to emigration and escape. We could include here detention centers for immigrants, customs posts, and refugee camps. The non-places of image are best exemplified in theme parks and tourist resorts – all virtually identical from one corner of the globe to the other.

The idea that the supermodern world is filled with simulacra is shared by other thinkers. It was another French scholar, Jean Baudrillard (1994), who employed the term *simulacrum* to define something which is not a copy of the Real but that actually exceeds reality and creates its own truth. This hyperreality of the supermodern Augé finds it not just in new constructions but also in the restoration of heritage, which creates a sort of historical hyperreality. What is interesting is what the anthropologist opposes to heritage sites: ruins. "The contemplation of ruins," writes Augé (2003: 7), "allows us to catch a fleeting glimpse of the existence of a time that is not the one about which history books speak or the one

that restoration works try to resuscitate. It is a pure time, to which no date can be assigned."

Although the existence of non-places has been questioned (Bender 2001: 78), it can still be argued that there are certainly spaces in supermodernity that if not totally devoid of identity, relationality, or historicality are at least hostile to the idea of memory and belonging. Archaeologists have started to study non-places in a way that is akin to de Certeau's (1984) approach to everyday tactics of resistance. Against the idea of monolithic non-places, researchers reveal the practices through which non-places can be appropriated and resisted. "The alienating qualities of these places are fragile: they can be challenged," argue Hicks and Hicks (2006). Without negating the dismal aspects of non-places, in this case a retail center in Wales, Graves-Brown (2007) also points out ways in which the physical barriers that enclose the "concrete islands" that are malls are circumvented in practice. Harrison and Schofield (2010: 256–257), in turn, suggest that archaeology itself can become a critical practice: if non-places are presented as neutral and ahistorical, archaeology has to reveal "the specific histories of these places and the ways in which they are concealed from the public. The peeling carpet, the layers of paint, and the traces of previous styles of airport furniture all carry a sense of the specific history of the airport departure lounge, signaling to the passenger that he or she is in 'this' place rather than some other." A similar approach is that of geographer Tim Edensor (2005), whose work has focused on another kind of non-places: abandoned industrial spaces. Although they are commonly perceived as a black hole in the urban fabric, Edensor shows that they are also arenas for creative engagements with materiality, where the regimented space of the supermodern city is actively subverted. The heterodox uses to which these ruins are put are a hint of another possible city and alternative urban experiences. While this is a valuable approach that can reveal an unexpected side to supermodern spatiality, we can wonder: do we not run the risk of overlooking the power structures that support the existence of non-places by trying to find small cracks in the system? How destabilizing to supermodern power actually are the paths open in the gardens of a shopping center, a peeling carpet, or the teenagers smashing windows in a derelict factory?

Non-places are just a variable of supermodern geographies. Other kinds of spaces exist. Bauman (2000: 98-104), following different authors, proposes a typology of mostly dystopic places, which he labels *emic*, *phagic*, and *empty* (in addition to non-places). Emic places create spatial separations (prisons, ghettos), whereas phagic spaces digest people and suspend otherness – consumer spaces fit in this category. Empty places are those that lack meaning, "leftover places." I have suggested a category of place that tries to make sense of the politics involved in the spatial excesses of supermodernity: places of abjection. Like empty places, they are also a leftover and a memory gap. However, it is important to emphasize that places of abjection are characterized by an excess of wasted materiality: battlefields, scenarios of massacres, industrial disasters, and shanty towns. When one walks around a war site of the last 100 years, one is struck by the enormity of material waste: concrete, cans, and shells litter vast expanses of empty, forgotten land (Fig. 2). A similar impression can be obtained in slums, whose messy material overabundance stands in stark contrast to the sanitized, empty spaces of privatopias (Penrose 2007: 34–35). Unlike other spaces of supermodernity, places of abjection are only produced by political processes of marginalization and exclusion of (subaltern) people, (abject) matter, and (dissonant) memories.

Time Excess

"The time is out of joint." Hamlet's words resound along Derrida's book, *Specters of Marx* (2006). "Time is disarticulated, dislocated, dislodged, time is run down, on the run and run down, deranged, both out of order and mad. Time is off its hinges, time is off course, beside itself, disadjusted" (Derrida 2006: 20). This is a more eloquent way of describing the state of time in supermodernity than the usual idea of accelerated time. Because it is not only that things go faster or that there is a factual excess, as Augé and others suggest. It is also, more precisely, that time is out of joint, which is also saying that time is both

Supermodernity and Archaeology, Fig. 2 An abandoned radar-guided antiaircraft weapon system (ZSU-23) in the rainforests of southwestern Ethiopia

unjust and anachronic (Derrida 2006: 25). Derrida, then, links temporality and morality, both of which are put into crisis by supermodernity.

It is probably this feeling that has led archaeologists to focus on alternative, heterogeneous temporalities (Witmore 2007; Hamilakis 2011), which are also a matter of concern in other fields (De Landa 2000). Archaeologists working in the recent past have to be, more than any other practitioners, ready to appraise nonlinear time to make sense of a world where time is deranged. They have to revalue other temporalities, those of subaltern and non-modern communities, which still survive in the interstices of the supermodern world. They have to make visible these slower, bodily temporalities, as a way to challenge the disarticulated ephemerality of supermodern time. A good way of reclaiming other temporalities is showing its persistence in the present, the time of objects that anchor time, instead of disintegrating it: the time of immutable things, which has been forgotten. Think of a knife, an axe, or a stone wall. They do not call the attention of students of material culture, which are fascinated by cell phones and tablet computers. An archaeology of supermodernity does not only study what is new and changing; it should also vindicate the subaltern artifact that resists the annihilation of time: the humble, elementary object (Olivier 2008: 288) (Fig. 3).

Because the time of supermodernity is not only disjointed and accelerated, it is also a time that continuously abolishes itself. For supermodern societies, there is no past or future: only the instant (Bauman 2000: 125). There is an excess of present. From the point of view of material culture, the relationship of this temporality with planned obsolescence and fashion has already been noticed. Archaeology can, of course, study the ephemeral temporality of supermodern technologies, but it can do something else. Archaeology can show the collateral damages of instantaneity: living the instant, with a total disregard for sustainability in the long term, requires an intensified predation on the environment, which leaves a far-from-ephemeral trail of devastation (cf. González-Ruibal and Hernando 2010). The ephemerality of material culture is certainly not new: it was already noticed at the beginning of the supermodern period, when skyscrapers in New York were torn down almost as fast as they were being built, over a 100 years ago (Yablon 2009: 244–246). The supermodern metropolis is hollowed out of a past; it inhabits an amnesic present. Connerton (2009: 88) talks about "the reign of a perpetual present." Here lies another possible contribution of archaeology: by excavating the foundations of post-mnemonic cities, the discipline can simultaneously show that other worlds are possible and that *there exists* a past.

Supermodernity and Archaeology, Fig. 3 Ephemeral consumption in the West, durable devastation in the rest: an illegal logging camp dismantled by the police in the Brazilian Amazon rainforest

Such an assertion, under the prevailing memory regime, can become a truly political one, especially if this past destabilizes the cleansed histories of progress or romanticized heritage pastiches (Hall and Bombardella 2005).

Material Excess

Material excess is one of the defining characteristics of supermodernity. However, sociologists and theorists have tended to downplay the relevance of matter and have preferred to focus instead on the less tangible aspects of supermodernity, either from a critical or celebratory point of view: networks (Castells 1996), fluidity (Bauman 2000), speed (Virilio 2002), and the virtual more generally. Capital flow, fast consumption, new media, and intercontinental travel give the impression that we are leaving a dematerialized existence: Bauman (2000: 113-118) talks about the shift from a "heavy" to a "light modernity." But is supermodernity truly that light? I would contend that, on the contrary, society has never been heavier and that to consider it light is the result of a process of purification, sensu Latour (1993), that black boxes the material foundations of supermodernity. I do not intend to rule out the metaphor of liquid modernity altogether, which I think is apt and insightful. The problem is that the metaphor can lead us to forget both the true weight of our present time and that this weight is not equally distributed. There are some regions of the world (those who suffer war or capitalist depredation) where supermodernity is heavier than in others.

The problem is that media gurus and journalists always tend to emphasize processes of virtualization. A good case in point is war, which is usually presented as a high-tech video game. Yet the combat gear of supermodern soldiers is bulkier than ever: only their body armor can weigh up to 15 k (Tyson 2009). And it does not matter how light a Predator drone is and that it is operated remotely; its effects are still strongly material and situated: rubble and splintered bones in a Pakistani or Yemeni village. Archaeology can be a counterbalance to the generalized perception of the world as plastic (Olsen 2003; González-Ruibal 2008: 252–254). An emphasis on fluidity and movement, in fact, may lead us to forget all the material strategies of fixation and circumscription deployed by supermodern powers: movement is always controlled. Those who move and the things that circulate have to be allowed to do so. It is a historical paradox that moments of high globalization come hand in hand with walls and fences: Hadrian's Wall, the Great Chinese Wall, the US-Mexico border fence, and the Israeli West Bank barrier.

Archaeologists have not been the only ones to have paid attention to materiality. Art has shown a

fascination with material excess for the last three decades at least. Godfrey Reggio's *Koyaanisqatsi* (1982) is a powerful audiovisual account of supermodernity, in which the mass production and mass destruction of materiality are repeatedly overlapped. A similar aesthetics is deployed by Andreas Gursky (2008) in his monumental photographs of cities, buildings, and crowded spaces and Burtynsky's (2009) equally vast depictions of supermodern landscapes altered to the extreme by heavy industry. These and similar works convey the impression of a deeply material world gone excessive, of superhuman scale and irreparable ecological damage and loss – things for which words alone cannot suffice: "a world beyond words" is the tagline of another visual experiment along this line (Fricke 1992). However, it is important to bear in mind that the art of supermodern destruction is an art of the sublime, with the ethical problems that this entails.

Burke (1834: 32) famously defined the sublime as "Whatever is fitted in any sort to excite the ideas of pain and danger, that is to say, whatever is in any sort terrible, or is conversant about terrible objects, or operates in a manner analogous to terror." Terror, in turn, is associated to power: power is sublime because it can inflict pain and terror and only when power is deprived of this ability, "you spoil it of everything sublime and it immediately becomes contemptible" (Burke 1834: 40). Yet the sublime is not only linked to terror and power but also to pleasure and beauty: "When danger or pain press to nearly, they are incapable of giving any delight, and are simply terrible; but at certain distances, and with certain modifications, they may be, and they are, delightful" (Burke 1834: 33). This is what the art of supermodernity achieves: it creates a distance with terror and pain that renders the destruction of the world produced by supermodern power aesthetically pleasurable and in the last instance, safe and consumable. This can be noticed in Dan Dubowitz and architect Patrick Duerden's exhibition: *Fascismo Abbandonato*. They have been documenting abandoned buildings of the fascist period in northern Italy, particularly youth camps. Theirs is an evocative vision of a failed modernist dream. As it happens with other similar undertakings, the exhibition is aesthetically powerful – but perhaps too much. There is an unabashed aestheticization of the subject. Thus, Duerden and Dubowitz describe the ruins as "huge and sublime" (http://www.fermynwoods.co.uk/archive/water-tower/dan-dubowitz-patrick-duerden/) – a description that would have pleased Mussolini. Herein lays the difference between the work of art and the work of archaeology. Although aesthetics are not absent – and do not have to be – in the archaeology of supermodernity (see Andreassen et al. 2010) as well as in critical artistic practice (Blocker 2009), in the balance between terror and beauty, it is terror and power that should prevail: disgust rather than pleasure. Consider two examples of supermodern excess: garbage and violence.

In William Rathje's research on garbage, there is little room left for beauty (of the conventional kind, at least): what we have are mountains of highly polluting rubbish or daily garbage fresh from the bin (Rathje and Murphy 1992). Likewise, the exhumations of victims of political violence disclose piles of bodies, an excess of shattered human matter, which has become a fossil guide for supermodernity (Montero 2009) (Fig. 4). However, archaeology does not only excel at revealing the abject: it also creates stories out of things – all things, no matter how humble or abject. With Gursky's photographs, we are left in awe, but this is a sublime awe similar to that produced by the manicured space of a military cemetery (Augé 2003: 103). Instead, by carefully dissecting ruins, locating artifacts, studying the relation of small objects and structures, and exploring the sites' afterlife, archaeologists can come up not just with a potent imagery but also with detailed narratives. It is powerful stories that we obtain out of garbage from a landfill, a mass grave, or the place of a disaster (Gould 2007). It is also this production of narratives that allows archaeology to construct a critical discourse on supermodernity, not just to stare at it in astonishment and powerlessness. Archaeology, thus, combines a concern for the manifestation of materiality, akin to art, and a commitment to analyzing reality, which relates it to other social sciences.

Supermodernity and Archaeology, Fig. 4 Victims of fascist violence during the Spanish Civil War. Exhumation by Juan Montero (2009)

Future Directions

Supermodernity has been defined here as a period within modernity characterized by excess. I have defended that archaeology can make a contribution to understanding supermodernity by looking into the excesses of time, space, and, particularly, materiality. While the overabundance of the spatial and the factual has often come under scrutiny, material excess has repeatedly escaped the gaze of theorists and it has mostly fallen to artists the task of manifesting it. Archaeologists, however, are in a good position to join artists in the examination of supermodern materialities. The study of late modernity has been too focused on the ethereal realms of hyperreality and virtuality: the complex semiotics of simulacra and networks have captured all the attention of scholars and philosophers. As opposed to this, I would argue that the mission of archaeology is to address the Real, sensu Slavoj Žižek: the Real is what resists symbolization, "the traumatic point which is always missed but none the less always returns, although we try – through a set of different strategies – to neutralize it, to integrate it into the symbolic order" (Žižek 1989: 69). Culture students abhor the Real precisely because it escapes hermeneutic efforts, but archaeologists are continuously facing the unconstituted, which is "not simply the unsaid, but the unsayable – it lies outside the said, outside discourse" (Buchli and Lucas 2001: 12). Referring to the Titanic, which has been transformed into a sublime object, Žižek (71) argues that "all the effort to articulate the metaphorical meaning of the Titanic is nothing but an attempt to domesticate the Thing by reducing it to its symbolic status, by providing it with a meaning." What archaeologists have to do is to expose the excess of supermodernity beyond symbolization: the raw, traumatic Thing at the core of the Real.

Surface Survey: Method and Strategies

Simon J. Holdaway[1,2] and Joshua Emmitt[1]
[1]Anthropology, School of Social Sciences, University of Auckland, Auckland, New Zealand
[2]University of York, York, UK

Introduction

Archaeologists developed surface survey methods in regions with abundant surface artifacts where these artifacts are visible today because of the action of a variety of geomorphic processes often leading to deflation (see ▶ Deflation Archaeology) or due to the concentration of artifacts near the surface. In regions of the Mediterranean, for example, cultivation means that fragmentary ceramics are often abundant and highly visible. Surface survey in the form of "plow zone" archaeology developed accordingly, allowing mapping of the distribution of ceramics as well as other artifact types and features like house mounds. In some regions of Central and North America, good surface visibility led to the development of similar approaches. In other regions, stone artifacts are abundant, and at times hyper-abundant, in surface deposits (Foley and Lahr 2015). In these cases, surface survey strategies have developed to analyze stone artifact distributions. More recently, the advent of technologies capable of detecting features like mounds beneath vegetation cover has enabled archaeologists to undertake surface survey in areas where surface visibility is poor because of vegetation cover. Surface surveys increasingly make use of electronic survey equipment, data loggers, and geographic information system (GIS) software.

Two broad strategies characterize surface surveys. Macroscale surveys seek to use the nature and distribution of sites to investigate political and economic relationships that operated over regional scales. These surveys are often based on recording the location, size, and composition of archaeological sites through the use of techniques described as "full-coverage settlement pattern survey." They make use of recording methods that enable the rapid acquisition of large numbers of records over areas measured in tens to hundreds of square kilometers (Feinman and Nicholas 2013). An alternative approach, named *Distributional Archaeology* by Ebert (1992) and *Off-Site Archaeology* by Foley (1981), adopted the artifact rather than the archaeological site as the recording unit. Here methods are used to characterize the differential density of artifacts as well as features across extensive spatial areas without the need to identify site boundaries. However, while the areas considered can be extensive, they are generally smaller than is possible with full-coverage type surveys.

Changes in the intensity of field survey correlate with the number of observations recorded.

However, increasing survey intensity comes at a cost since the more time spent surveying in one area potentially leads to a smaller spatial extent of coverage. Criticisms leveled at *Distributional Archaeology* reflected the issues dealing with this relationship (Bettinger 1993), and surveys directed at recording artifact density in the Mediterranean region attracted similar criticisms. Critics commenting on studies from this area complained that some intensive surveys were too small in extent to reveal useful socioeconomic interpretations (e.g., Blanton 2001; Kowalewski 2008). Caraher et al. (2006) summarized the subsequent debates concerning whether a myopia, to use Blanton's (2001) term, in favor of intensive data collecting led to surveys that covered insufficient spatial extent to identify regional patterns.

The ability to conduct surface survey certainly relates to visibility and spatial extent, but the strategies and methods adopted depend on how data acquired during survey are analyzed, and this of course depends on the types of research questions asked. In the following, we consider three broad topics. First, we review examples of surface survey noting the techniques that archaeologists have adopted to characterize surface archaeological remains. We compare studies conducted in the Mediterranean region with those undertaken in both the Mesoamerican highlands and lowlands. Second, we consider methods of analysis applied to these observations. Surface archaeological remains are frequently more abundant than buried remains simply because of their accessibility. It takes more time to excavate material than it does to record material that is visible on the surface. Large numbers of observations from surface deposits make it possible to detect patterns in the distribution of both objects and sites. However, the processes that lead to formation of the archaeological record are often complex and not always directly related to the activities of people. Blanton's interest in understanding macroscale patterns therefore relies on the ability to define an unambiguous set of analytical procedures that progress from the form and abundance of surface artifacts and features up to inferences about such things as the numbers of people who occupied different parts of the landscape at different times or the nature of hierarchy in social organization. Analytically, it is important to understand the degree to which it is possible to upscale from the distribution of archaeological materials to infer sociocultural process. Third, the quantity of data acquired through surface survey produces logistical challenges but also new opportunities. Using case studies based on our own research, we review the application of new technologies, the use of which means that both the number and the types of observations made have greatly increased. Technological developments also mean that the types of analyses open to archaeologists have also expanded.

Archaeological Surface Survey

Archaeological surface survey in the Mediterranean region is now more than three decades old with good consensus on methods used, the types of sampling employed, and the significance of off-site versus site-based survey (Given 2013). In an earlier study, Cherry (2003), for instance, combined probabilistic designs with systematic, pedestrian survey on Melos, Greece, involving surveyors separated by regular intervals, walking across the land surface, recording exposed artifacts. Transect lines 1000 m wide, orientated north-south, were staggered across the island. The typology of artifacts, established through earlier excavations, provided a chronology, while the assessment of the probable function of the artifacts in the field provided an indication of the functional status of the sites identified. In another example, the Troodos Archaeological and Environmental Survey Project (TAESP), archaeologists surveyed an area of 164 km^2 broken into six zones that represented different topographic regions. Within these, recording focused on survey units rather than sites. With dimensions of 25×50 m, the survey units were spaced in long transects at right angles to the main water courses. Collection involved obtaining a representative sample of pottery, all chipped stone, and a selection of other cultural materials from within these units. Where the identification was made of dense

concentrations of material, artifacts were collected across contiguous units (Given 2013).

This basic scheme characterized later projects although the intensity of survey (as measured, e.g., by the spacing between field walkers) and the tendency to survey continuous blocks rather than transects changed as did the concern for processes that might have altered or obscured the surface archaeological record (Bintliff 2000). Tataron et al. (2006), for example, reported on the methods used in the Eastern Korinthia Archaeological Survey (EKAS) where investigation involved an area of 350 km^2 east of the ancient city of Corinth, Greece. The survey design paid particular attention to the geomorphology of the region including consideration of the post-depositional processes that had a potential impact of the position and preservation of artifacts and features. In advance of the archaeological survey, geomorphologists mapped soils, sediments, and faults at a range of scales, from drainage basins to localized geomorphic units. Use of a GIS enabled the integration of contours, landforms, geology, hydraulics, and tectonics with cultural features like sites, burials, and roads. The survey used a stratified sampling design, with the study area divided into environmental zones initially based on six major drainage systems permitting a regional survey. This allowed the definition of what were termed morphostratigraphic units, landforms reflecting tectonic, alluvial, colluvial, or littoral processes. Within these, survey involved the identification of geomorphic units defined as distinct pieces of the landscape that reflected the action of a single geomorphic process either natural or cultural (e.g., bulldozing). Archaeological survey involving three different approaches made use of these geomorphic units. Initially, survey involved the use of tracts called Discovery Units, where surveyors spaced at 10-m intervals inspected 2-m-wide swaths counting the artifacts they encountered and collecting samples according to a chronotype system (described below). Investigation of these Discovery Units occurred within a selection of environmental strata. In addition to the Discovery Units, Localized Cultural Anomalies provided the means to describe clusters of artifacts and/or features different in extent to the surrounding density of material and where this clustering was not due to geomorphic processes. The third investigation unit, the Extensive Discovery Unit, described areas where it was not possible to implement the intensive, systematic, Discovery Unit approach. The system allowed the integration of geomorphic processes in different parts of the survey area with records of the number and nature of archaeological objects and features. These data in turn permitted assessments of landscape stability, and therefore the depositional history of the artifact surface scatters at a fine spatial scale.

Within the Discovery Units, pedestrian surveyors walked 10 m apart counting and collecting artifacts using the chronotype collection system. This system provided both a classification method for artifacts and a collection protocol. Following the system, surveyors picked up one example of all artifacts encountered leaving behind those with the same material, shape, and decoration. Collection involved all items in the case of rarer types such as lithics, metal, and glass. For classification, the seven classes initially identified, pottery, stone/lithics, metal, glass, terracotta, shell/bone, and other, were further subdivided reflecting function and chronology. A separate team considered the artifacts retrieved and conducted further analysis, classifying these and removing any duplicates. According to the authors, the system works well in regions with large quantities of pottery where total collection is not feasible (e.g., Meyer and Gregory 2003; Gregory 2004). Analyses of the data acquired in this way involved calculations of the number of artifacts per area surveyed in relation to environmental data sets collated using GIS software.

In Mesoamerica, William Sanders, as part of the Teotihuacan Valley Project, first implemented regional surveys in 1960 with the methods he developed. Sanders expanded the use of these methods to other parts of the Valley of Mexico over the ensuing decade in collaboration with others like Jeffrey Parsons and Richard Blanton. The Valley of Mexico project set the standard for Mesoamerican regional surveys with subsequent surveys extended to the central and southern Mexican highlands (Feinman and Nicholas

2013). For example, survey in highland Oaxaca and the adjacent Mixteca Alta reached a combined area of approximately 8,000 km^2. Working in one part of this area, Feinman and Nicholas (2013) reported on the results of a survey of the Ejutla Valley, adjacent to Oaxaca, conducted during the 1980s, before the widespread use of mechanized farming machinery. Vegetation at the time that the survey was undertaken was light, and consequently, the majority of the land surfaces had high visibility, permitting rapid identification of archaeological materials. Survey involved crews systematically walking fields and marking sites identified onto aerial photograph mosaics. It also involved mapping features such as mounds, platforms, plazas, walls, and terraces directly onto the photographs together with their site boundaries. Recording consisted of descriptions of artifact form, frequency, and location, together with datable diagnostic pottery and sherd density. In addition, a series of observations were made concerning contemporary land use and erosion/deposition, as well as environmental variables like distance to water and soil color and texture.

In these surveys, less attention was given to the type of fine-scale details related to artifact visibility recorded, for example, by Tartaron and colleagues (2016) working in Eastern Korinthia, Greece. In the surveys like those conducted by Feinman and Nicholas (2013), following the methods developed in the Basin of Mexico, increasing spatial extent provided the primary motivation rather than investment in the extended study of the influence of fine-scale differences in visibility. Stark and Garraty (2008), however, did investigate the impact of visibility conditions on their landscape survey results for the western Lower Papaloapan Basin in the Gulf lowlands of Mexico. They used visibility records to help estimate the number of archaeological features not recorded during survey when considering residential earthen mounds and concentrations of domestic artifacts. Stark and Garraty recorded a variety of vegetation categories and showed how, even in what they referred to as "full-coverage survey," the area investigated should be considered as a sample, dependent on the size and obtrusiveness of artifacts and features, the intensity of survey coverage, and the variation in visibility across the landscape.

Other studies have shown how different processes affect survivorship of the archaeological record and hence its visibility, both at the scale of the archaeological site and at that of the individual artifact (Bintliff 2000; Terrenato 2004). Pottery, for instance, degrades with age, depending to some extent on its manufacture. Therefore, ancient sites may be less visible than those that are more recent. The complexity of the natural processes involved in any one region means that their impact needs consideration on a case-by-case basis. Equally important, some activities in the past led to the deposition of many artifacts, while others produced many fewer objects. Therefore, comparisons require careful consideration of density measures.

Varieties of approaches have developed to assess the processes that pattern the surface archaeological record. Some of these relate to cultural behavior in the past, but patterning may also result from natural processes, and different patterns are visible at different spatial scales. Markofsky and Bevan (2012), for example, report on techniques used to assess differential visibility in the Murghan Delta in southeastern Turkmenistan. In this region, alluvial fans result in complex patterns of hydrology and dune cover that complicate interpretations of artifact density. Infrequent heavy rains combined with winds act to deflate sediments and thereby redistribute surface material. Markofsky and Bevan illustrate analyses designed to assess the degree to which ceramic sherd counts show patterning in some directions more than others do (i.e., are anisotropic). Two techniques are used, directional and surface variograms, both of which permit the assessment of spatial variation over multiple distances and in different directions and angular wavelet analysis that permits the analysis of angular variation between individual surface sherds. Within the Murghan region, sand dunes are orientated north-south, while the paleo-delta is orientated northwest, with paleo-channels approximately following this orientation. Visual assessment of these anisotropy were checked using Advanced Spaceborne Thermal Emission

and Reflection (ASTER) satellite data with variograms showing the strongest autocorrelation in the directions ranging from N-S to NNW-SSE. Application of the variogram technique enabled assessment of the distribution of ceramic sherds recorded in the study area. The analysis showed anisotropy at distances up to 4–500 m but with considerable local variability. Application of wavelet analysis to pottery assemblages separated chronologically showed change in the nature of anisotropy through time. Bronze Age pottery showed no clear anisotropy in the northern part of the survey area; however, Sasanian and Islamic pottery showed strong east-west anisotropy in the same region. The authors propose that this difference in pattern may relate to a present-day road that might have followed the route of more ancient tracks, perhaps reflecting an east-west trading corridor. Pottery concentrations aligned to this road.

In our own work, we have also paid particular attention to the types of geomorphic as well as cultural processes that might have an impact on the visible surface archaeological record. In western New South Wales, Australia, for example, eroded areas termed scalds were formed when the uppermost sediment layer was removed by erosion, exposing the underlying layer which is commonly saline (Fig. 1). A soft, puffy, crust typically forms which readily breaks down with trampling by modern domestic stock (Charman and Murphy 2000). Erosion removes fine sediments but typically leaves the larger clasts intact including stone artifacts. Scalds therefore form physically bounded areas that have high archaeological visibility. In effect, they act as small excavations distributed across the landscape with the majority of the artifactual material remaining in place. Since the scalds formed because of erosion, their location is effectively independent of the activities of the Aboriginal people who were responsible for manufacturing and discarding the artifacts. They therefore form suitable ready-made sampling units with which to investigate large areas.

Surface Survey: Method and Strategies, Fig. 1 Scald from western New South Wales, Australia, used as a sampling unit in survey. Erosion provides a window into the distribution of artifacts across large areas

In our survey work, we studied a random sample of the scalds from one drainage feature, Rutherford's Creek. In each scald, a geomorphologist drew a line separating eroded from intact sediment. Within this perimeter, lines were drawn to indicate patches of soil, vegetation, and ant nests together with any modern activity such as vehicle tracks. As well, the boundaries of any watercourses were marked out (Fig. 2). All lines were digitized by a total station positioned using a differential GPS. Once the digitization of lines was complete, artifacts over 20 mm in maximum clast dimension were identified and described and their locations mapped. In a series of studies, we assessed the impact of these localized geomorphic features on artifact visibility and location (e.g., Fanning and Holdaway 2004), scaling the processes up to account for both the presence and absence of artifacts at different points in the landscape (e.g., Fanning et al. 2009) and to patterns in the chronology of cultural materials (e.g., Davies et al. 2016). Analysis of the pattern created when radiocarbon dates obtained from surface hearths were combined showed that both the increase in the frequency of dates toward the present and oscillations in the number of dates in adjacent periods are likely reflected periods of erosion and burial as a result of episodic rainfall rather than culturally related processes like local population shifts (see ▶ Deflation Archaeology). Thus, in the case of western New South Wales, it is possible to show that visibility at the microscale accounts for some of the patterning visible at the macroscale. In such situations, it is important that

Surface Survey: Method and Strategies, Fig. 2 Surface features together with stone artifact locations mapped in a scald used as a surface survey-sampling unit in western New South Wales, Australia. Black dots represent artifacts and hatched area represents sediment islands and single line shade water courses

archaeologists undertake local-scale visibility studies before making cultural inferences from the nature of macroscale patterning.

Comparing patterns generated by natural and cultural processes exposes archaeologists to the challenges posed by **equifinality** (following Dincauze 2000 rather than the strict definition – see Rogers 2000). People certainly created artifacts and features in the past, but the patterns these items form in the archaeological deposits on both the surface and in buried deposits do not necessarily relate solely to past human activities. The way the archaeological record accumulates and is transformed forms patterns in material remains that may at times appear as though they relate to human activity when in fact they relate to geomorphic processes. It is therefore important to understand how processes that affect visibility scale up to have an impact on broad-scale inferences that archaeologists make about things like past settlement patterns, social hierarchies, and population numbers. As studies like those we conducted in Rutherford's Creek and more generally in western New South Wales, Australia, show, increasing the spatial scale does not always negate the impact of differential visibility. To use Blanton's analogy, while detailed study of the impact of differential local visibility may appear myopic, such studies must be undertaken since interpreting regional patterns at face value, without considering the impact of local processes, may lead archaeologists to incorrectly interpret regional patterns that relate to natural processes as if they reflected large scale, human behavior.

One of the most dramatic examples of the significance of dealing with the impact of differential visibility comes from recent work on surface archaeological remains in lowland regions of Mesoamerica. In some of these areas, dense forest has led to limited opportunities for surface survey and therefore site identification. However, new technology in the form of airborne LiDAR (see ► Aerial Archaeology) is changing this, since it is now possible to visualize not only larger architectural examples but also quite low features

including mounds, terracing, and underground storage units. This new evidence is changing previously held beliefs about the nature and extent of occupation in previously inaccessible areas (Chase et al. 2012). Rosenswig et al. (2013), for example, used LiDAR data to locate 670 mounds in the Soconusco region of southern Mexico. They checked identified mounds using foot survey across an area of 43.1 km^2. Based on the correlations obtained comparing LiDAR and conventional survey, size estimates for the area of the site of Izapa utilized during the Late Classic period tripled. In a separate study, Fisher et al. (2016) reported on the archaeological settlement pattern for the Mosquitia region of Honduras. Using airborne LiDAR permitted the detection of anomalies on the surface larger than 1 m on a side and greater than 50 cm height. Results of the LiDAR survey indicated considerable cultural modification of the area in the past with both terraces for agriculture and habitation together with water control features constructed. The identification of 19 settlements was possible in a variety of geographic settings in addition to a single larger site with an area of 142 ha composed of 10 plaza complexes. As with similar studies, discovering the number and extent of features in areas today covered by vegetation is changing previous conceptions of the nature and extent of past settlement patterns.

The increase in precision obtainable with LiDAR data is also changing estimates of the numbers of archaeological sites from those based on direct field observation using older technologies like aerial photographs. In a LiDAR study of the Kohala field system, Hawaii Island, for example, Ladefoged et al. (2011) reported how, compared to an earlier study, the use of LiDAR increased estimates of the density of alignments in field systems from 614 m/ha to 850 m/ha. They also reported how the LiDAR data permitted greater understanding of the distribution of alignments than was previously possible, as well as the accurate identification of the relationships between trails and agricultural alignments.

As illustrated by Mosquitia study, it is important to understand when archaeological features are truly absent versus those simply hidden from view. However, as some of the other examples also illustrate, it is also important to understand how the distribution of archaeological materials may result from the action of processes other than peoples' past behavior. In some studies, there is evidence that differential visibility as well as increased accuracy of recording of archaeological features may scale up from the micro to the macro leading to different conclusions about the distribution and complexity of past activities. This indicates that the visibility of the surface archaeological record needs to be carefully analyzed before making inferences about past use of the landscape.

Analysis of Surface Survey Results

Menze and Ur (2012) introduced their study of mound sites from the Upper Khabur Basin of Hassake Province, northeastern Syria, with the observation that survey archaeology involves a trade-off between the need to survey areas extensive enough to discover pattern with the need to survey intensively at the local scale to discover small sites. As they suggested, initially many archaeologists dealt with the first half of this dichotomy, while in more recent times, the latter half has also become of interest. Their solution to resolving the dichotomy is to adopt the use of satellite imagery, which they used to investigate an area in Mesopotamia measuring 22,000 km^2. In their study, they focus on the volume of mounds since calculation is possible from a digital elevation model derived from the satellite data. Volume provides a proxy for the long-term attractiveness of settlement locations. They made use of multiple satellite images taken at different times to verify that mounds identified in the images were similar to nearby known archaeological sites and to remove short-term surface variation. When combined, the results from the analysis of multiple satellite images resulted in the identification of 14,312 sites. Verification compared high-resolution Satellite Pour l'Observation de la Terre (SPOT) and Central Intelligence Agency Directorate of Science and Technology (CORONA – a code word not an acronym)

satellite image data and with data derived from archaeological surveys in the region. Use of the Shuttle Radar Topography Mission (SRTM) digital elevation model enabled mound volumes to be calculated. Using the number of sites per area, the volume of all sites per area, and the average volume of sites per area, comparisons were made with drainage classification, all three quantities showing a positive correlation.

The patterns that Menze and Ur (2012) detected suggest long-term arrangements in the way settlements were located in Mesopotamia. However, as the Markofsky and Bevan (2012) study outlined above shows, macro-regional patterns do not always reflect the actions of people in the past. Processes that lead to differential visibility in the location of archaeological materials but also their size and form can create distributions that look as though they represent past settlement patterns. Simply increasing the spatial scale of observations, as advocated by some (e.g., Kowalewski 2008), does not overcome this problem.

Bevan and Conolly (2009) discuss the issues involved in understanding patterns observable at different spatial scales using the concept of the **modifiable area unit problem**. The "problem" in this concept arises because with aggregated data, observable spatial patterns are dependent on the spatial scale used, and therefore the choice of aggregation unit becomes important in determining the nature of the patterns seen. Where densities of material culture vary, relationships that may be apparent at a particular spatial scale in one area may not be apparent when the scale and/or the area is changed. Bevan and Conolly report on the results of the survey of the entirety of the Greek island of Antikythera. Here they note that two patterns in the distribution of pottery are apparent when measured at different scales. At the local scale, differential pottery density relates to the existence of small, dense areas approximately 100 m across which tend to cluster together with clusters separated by emptier areas. At a regional scale, higher and lower densities align with prevailing tectonic fault lines running in a NW-SE direction. The later pattern also correlates with a number of environmental variables like soils, slope, elevation, and hydrology. Behavioral inferences based on these different patterns need to be carefully made. The choices people made in the past to locate their activities in different places were certainly at times influenced by environmental variables, but these same variables may influence archaeological site visibility, and these two processes need to be carefully considered if they are to be differentiated.

Bintliff et al. (2006) discuss examples from survey work in Boeotia, southern Greece. Here patterns of ceramic visibility relate to chronology and sherd survival. In their study, investigation was based on Sherratt's (1980) suggestions about site distributions as part of his early farming model. According to the Sherratt model, both the secondary products revolution (i.e., the development of dairy and wool production) and olive cultivation provided opportunities for increased agricultural production in southern Greece. However, the results obtained from surface survey produced pottery concentrations from Classical Greek and Roman age sites without such pottery concentrations identified dating from the Neolithic or Early Bronze Age periods. Bintliff et al. (2006) explain this absence by considering both the nature of pottery discarded at different periods and the processes that led to pottery discard. Classical Greek pottery survives well in contemporary plowed soils, whereas Neolithic and Bronze Age potsherds were made from a coarse pottery fabric and therefore have poor survival. As well, during Classical times, large quantities of sherds transported away from Greek cities were included in the manure deposited in fields adjacent to settlements. Within the area surveyed, numbers of these sherds exceed one million. Therefore, they tend to swamp the small number of sherds that survive from earlier periods. Bintliff et al. (2006) note how only small numbers of Bronze Age sherds are present in collections retrieved from areas with dense concentrations of sherds with later dates. They argue, therefore, that surface scatters with small numbers of older aged sherds may today represent early farmsteads, with the sherds found being in poor condition. These sherds provide the evidence for Sherratt's (1980) early farming. Following this line of

argument, Bintliff et al. (2006) modified their strategy when undertaking survey near Tanagra where manuring has also led to the deposition of many sherds from Classical times. Collections were made of all sherds with particular emphasis on the identification of coarse body sherds. Analysis of the resulting distribution indicated a 2-km-long stretch where Neolithic sherds were recovered in an area with perennial streams that conformed to some degree with the predictions from the Sherratt model.

In the Ejutla Valley example discussed above, Feinman and Nicholas (2013) estimated population numbers represented by every site following the procedures developed by Sanders and Parsons for the Valley of Mexico survey. The calculations used the assumption that the area of a site and consequently the ceramic density on the site related to the number of people who occupied it. With the addition of mound volume, these measures provided population size estimates organized by temporal phase and geographic location, which in turn provided the means to infer mound and population size hierarchies for each temporal phase. These allowed the consideration of social organizational change through time including the centralization of political power.

While analyses of the type used by Feinman and Nicholas (2013) provide the means to investigate macro-regional settlement pattern change, using ceramic typologies to provide chronologies, care is needed in assessing the analytical steps that lead to estimates of past population levels and political complexity. An increase in the frequency of observations through time may appear to show population increase. However, as the Australian hearth example discussed above illustrates, geomorphic processes that determine the burial and exposure of hearths, and therefore the ability to obtain radiocarbon determinations, can create patterns very similar to those that are attributed to population increases when analyzed in some macro-regional studies (Davies et al. 2016). Even if differential visibility can be accounted for, including such things as the survivability of the artifactual material, as Duffy (2015) points out, there are varieties of behavioral causes for distributions of sites that display site size hierarchies that do not involve examples of political centralization. Duffy's study illustrates some of the issues surrounding equifinality that are of a concern in archaeological interpretation. It is important to consider how the "modifiable unit area problem" discussed above may have an impact on the patterns generated at different spatial scales and therefore the types of explanation that archaeologists derive from surface survey.

Case Studies

In our own research in Australia and Egypt, we have confronted the issue of how to assess both the distribution and composition of artifacts recorded in the sampling units in ways that reflect some of the issues discussed above. At Rutherford's Creek, western New South Wales, Australia, for example, the composition of the artifact assemblages in the scald sampling units recorded from the headwaters of Rutherford's Creek to where it discharges into Peery Lake showed variability in artifact density but not in a way that aligned with the length of the creek line (Holdaway et al. 2012, 2015). Instead, analytical results related variability in density to two processes, one linked to the nature of environmental change and the other being a result of human behavior. Artifacts accumulated on surfaces along the valley floor of Rutherford's Creek and were visible following erosion, enhanced in recent times by the presence of European introduced domestic livestock that created the scalds used as sampling units discussed above. However, analysis of the surface area and volume of the stone artifacts recorded throughout the length of the valley indicated that a considerable proportion of the flakes originally struck from locally available cores were missing (Douglass et al. 2008). These flakes, likely selected for their size, were transported over distances, and therefore for periods representing their useable life, of such a magnitude to ensure that they were never returned. Transport in this way acted as a proxy for human movement. The stone artifact assemblages that remained reflected assemblages of objects left behind after flake removal. Items carried away

indicated those artifacts deemed to be useful for activities conducted elsewhere in the wider landscape. Obviously in this situation, using counts of the artifacts that remained, or the degree to which they were concentrated or dispersed, as a measure of the intensity of occupation or the size of the population that occupied a location would not be wise. The artifacts that remained represented only a sample of those manufactured, and indeed, many of the retouched tools found abandoned by people as they moved through the valley deposited at the end of their uselife may have been made and used at locations well away from Rutherford's Creek (Douglass et al. 2017).

In understanding how to analyze the relationship between the surface artifact distributions we recovered from Rutherford's Creek in relation to aspects of the environment, attention focused on both manufacture and the processes that led to their visibility. Understanding of the patterns in the spatial distribution of artifacts identified through surface survey in this case study derives from what is missing as well as what is present. Similarly, the environmental context needs to be interpreted in relation to the outcome of a series of processes operating through time rather than a constant state. Analysis of satellite data, SRTM and Landsat Enhanced Thematic Mapper (ETM), provided measures of the topographic complexity of the study area as well as contemporary variability in vegetation and regolith. These data sets, in combination with past and present environmental assessments (Holdaway et al. 2013), indicated the context of past environmental resource abundance. In western New South Wales, resource heterogeneity did not translate into the formation of regularly recurring resource patches, largely because of low soil fertility combined with climatic variability. Australia is characterized as having an "infertile, well sorted landscape" (Stafford Smith and Morton 1990: 261). Long periods with little or no rain separate short periods of very abrupt rainfall. At the same time, Australian soils are depleted in nitrogen and phosphorous, largely because of the continent's tectonic history (Morton et al. 2011: 317). Lack of fertility and intermittent rainfall thus combined to produce a landscape that varies both spatially but also temporally in ways that were not easy to predict. This lack of predictability in environmental resource heterogeneity meant that a location rich in resources at one moment in time might become depleted at another, with little way of predicting when such a change might occur. If resources were episodic in their availability, both spatially and temporally, many places would see at least some use and therefore would see the creation of an archaeological record. Using a "dots on maps" approach, where the location and abundance of past activity are interpreted directly from survey results, the landscape would appear to consist of a carpet of occupation debris, as though all places were used at once. In fact, the opposite is the case; this carpet of dots is instead a signature of high mobility by small numbers of people in a landscape where the ecology and topography lead to the wide dispersal of the material remains of occupation.

Image analysis gives the wider landscape context to the archaeological record from Rutherford's Creek. The low redundancy in place use, as evidenced by the variety of ages and the abundance of hearths, indicates how multiple places saw use, but no one place at levels significantly higher than its neighbor. Similarities in assemblage composition also indicate low redundancy in place use. Analysis of the stone artifacts indicates movement through flake removal, suggesting high mobility consistent with the need to move often, and far, to find the resources that became available through time, rather than the prolonged used of residential occupation sites.

In a different study, we considered the evidence for movement in the composition of artifact assemblages from the Fayum, Egypt. The Fayum consists of a depression with a lake, Lake Qarun, and the near lake-edge surrounding environment. Caton-Thompson and Gardner (1934) made the Fayum famous because of their work during the 1920s close to Lake Qarun's northern shore. They discovered a record of both stratified and surface sites, the latter consisting of extensive distributions of stone artifacts, ceramic sherds, animal bones, and hearths. However, their publications described the stratified deposits, with only a brief

description of the composition of some of the surface scatters. Most recently the area was reinvestigated by the University of California, Rijksuniversiteit Groningen, University of Auckland (URU) Fayum Project (Holdaway and Wendrich 2017). The project extended approximately 20 km along the north Fayum lakeshore with an area of circa 142 km^2.

While some new excavation occurred, one of the main objectives was to survey and understand the distribution of surface material away from stratified deposits. Also investigated was the potential relationship between the nature and extent of settlement and the extent of Lake Qarun that fluctuated in size in the past during the early and middle Holocene.

Caton-Thompson and Gardner identified six basins along the north shore with these incorporated into the survey design. Assessment of the size and extent of these basins was made using data from the ASTER global digital elevation map and a 1 m resolution digital elevation model generated from satellite-derived Worldview-2 stereo imagery (Phillipps et al. 2016). To determine changes in assemblage composition and density away from the basins and the paleoshoreline, four corridors were surveyed orientated north-south from the Lake Qarun paleoshoreline. These corridors were 100 m wide and were walked by surveyors spaced 10 m apart. Survey along the corridors enabled hearths and grinding stones to be located using differential GPS. In addition, detailed survey for portable material culture was made using transect survey units located using a logarithmic scale at 100 m, 200 m, 400 m, 800 m, 1600 m, 3200 m, and 6400 m north from the paleoshoreline (Figs. 3 and 4). Survey transects consisted of a cross, 10 m wide with four

Surface Survey: Method and Strategies, Fig. 4 Walking survey in the Fayum. (Photo courtesy of S. J. Holdaway, Fayum URU Project)

arms 50 m long, orientated north-south, east-west. Transect units were recorded in two ways. Following a similar method to that employed with the eroded scalds described above in the Australian case study, different sediment types and areas of surface disturbance were initially drawn on the surface and subsequently recorded with a total station positioned with coordinates derived from a differential GPS. Second, every artifact within the transects with a maximum dimension size over 20 mm was recorded in position. To investigate the potential issues related to visibility and preservation, the differential densities of artifacts were calculated for each surface type and for each transect. Results indicated that artifact densities varied considerably according to sediment type. Wind-blown sand, for example, covered artifacts thereby reducing artifact densities. For this reason, artifact densities from high-visibility surfaces (e.g., consolidated sand and gravel surfaces) were used to compare artifact densities within transects in each of the corridors. Many transects contained either none or very few artifacts, even accounting for surface type. This showed that taking account of differential visibility, artifacts were concentrated near the lake basins originally identified by Caton-Thompson and Gardner.

Transects were also used to survey areas close to the K, L, and X Basins (Fig. 5) (Holdaway and Wendrich 2017). In these areas, transects were spaced around the basins and stratified deposits, such as Kom W, forming a systematic grid with additional transects used to survey areas of artifact concentration. Similar patterns of artifact visibility were observed based on mapping sediment types within the cross-shaped transects. After mapping sediment types and artifact locations, artifacts from sample transects were fully analyzed. Data loggers in the form of portable computers enabled recording of the size, shape, and technological variables on all artifacts with a maximum dimension of 20 mm or more. Once recorded, artifacts were returned to the place from where they were found, a practice used in other projects (e.g., Tartaron et al. 2006). Treating artifacts in this way has obvious positive heritage management implications since the archaeological record remains for others to study in the future

Surface Survey: Method and Strategies, Fig. 5 Transects positioned around the K, L, and X Basins. (Figure courtesy of S. J. Holdaway, Fayum URU Project)

Surface Survey: Method and Strategies, Fig. 6 Infield stone artifact analysis in the Fayum. (Photo courtesy of S. J. Holdaway, Fayum URU Project)

but also has significant logistical advantages since there is no need to curate large artifact samples (Fig. 6). However, recording in this way is very dependent on technology with a combination of raid and precise surveying equipment to locate artifacts and portable data loggers with which to record observations about the artifacts. The other key technology is GIS software that enables the organization, display, and analysis of multiple types of data (from satellite imagery and elevation models to artifact dimensions and material source data). This software has greatly enhanced the ability to move seamlessly between the scale involved in assessing local visibility and the scale needed for regional environmental reconstruction.

Stone artifacts dominated the Fayum assemblages recorded with the majority manufactured from flint. This material does not occur naturally in the Fayum Basin, indicating the movement of raw material for flaking into the area from elsewhere. Like the stone artifacts from surface deposits in Australia, measurements of stone surface area and volume indicated the movement of stone artifacts into, within, and away from the Fayum Basin. When combined with the results of the analyses of pottery, faunal, and floral material, movement, possibly on a seasonal basis, is indicated in the Fayum, following a settlement pattern like that which Wengrow (2006) characterized as a horizontal tell, rather than prolonged occupation of individual villages.

Discussion and Conclusion

Surface archaeological deposits have the potential to answer questions concerning how people used space in the past providing the data needed to answer the types of research questions, for example, posed by landscape archaeology. However, the same exposure that provides archaeologists with access to extended spatial distributions of artifacts without the need to undertake time-consuming excavation has also encouraged methods that are spatially extensive rather than locally intensive. Artifacts often show pattern at different spatial scales leading to the problems posed by equifinality as well as issues connected with the modifiable area unit problem. There are multiple processes that lead to objects showing spatial patterning, and while some of these relate directly to human behavior, others relate instead to the operation of natural processes or indeed to some combination of the two. While it is often tempting to look for the types of broad-scale pattern that suggest potential inferences about past population levels, social complexity, and occupation duration, it is often not possible to assume that an increase in spatial scale will offset pattern induced by differential visibility caused by natural processes. The number of studies that document the alteration of the visibility of surface archaeological deposits (or indeed buried deposits) by non-cultural processes indicates that claims of myopia when studies concentrate on documenting the local impact of artifact visibility may be misplaced.

Dealing with spatially extensive surface deposits involves the integration of many forms of data making the application of GIS increasingly fundamental in surface survey. To some degree, these same software systems are helping to overcome the perceived dichotomy between spatially extensive and locally intensive survey (McCoy and Ladefoged 2009). When combined with modern survey equipment, like GPS and total stations but also portable data loggers, it is now possible to record rapidly a wide range of information. Moreover, with GIS it is also possible to move seamlessly from the local to the regional spatial scales. Adding satellite and LiDAR data to the mix, it is also possible to acquire regional data sets including in some instances data that was previously irretrievable because of dense vegetation. These technologies mean that there is much less need to see study at the local scale as achievable only at the expense of the macroscale. Archaeologists have the potential to gain the best from both scales although of course this means they need to acquire multi-scale data. As the examples and case studies discussed here help to illustrate, at worst the issues raised by equifinality and the modifiable area unit problem can be better defined, and at best they can be solved. Ultimately, this will lead to better answers to the interesting questions that archaeologists ask about the past, how settlement patterns varied through time in relation to changing socio-economies and social relations. Surface archaeological deposits are abundant in many regions of the world, and with advances in survey and recording technology, their potential to inform about the past has only just begun to be realized.

Survey Archaeology in the Greek Aegean World

John Bintliff
Institute of History, Leiden University, Leiden, The Netherlands

The development and current nature of Greek field survey can be divided into chronological stages and a number of contemporary methodological and theoretical issues. We define field survey as the systematic study of the surface remains of past human activity across the landscape, comprising chiefly potsherds and lithics but including building remains and field systems.

THE FIRST ERA, from the seventeenth to mid-nineteenth centuries, is the age of the "Travellers" and their "topographic round" in search of visible remains of sites known from their reading of the Greco-Roman sources. These detailed travelogues (e.g., Wheler and Spon 1682; Leake 1830; Ross 1851) are still useful in the field as they indicate ruins since demolished and ancient sites that frequently are found to have been first occupied in prehistoric times. Moreover, they can provide detailed records of contemporary society and lifeways in the communities they visited. In essence scholars of the Classics wished to find material traces of the towns and landscapes, sanctuaries, or battlefields, known to them in their libraries of ancient authors. This was for their own enjoyment but also to offer travels in the imagination to armchair readers of their travel guides back in temperate non-Mediterranean Europe.

Caution is required if one uses them today: some merely copy what others had written or

offer fanciful reports. However additionally many sketched or painted what they saw or took artists along with them, and these both assist us to identify monuments, usually in a better state at that time than today, and record the landscape, land use, and settlement forms of the final centuries before the modern era (Tsigakou 1981). Moreover, they can still offer surprise discoveries: in 1805 the English traveller Edward Dodwell with his Italian artist visited the ancient city of Haliartos in Central Greece (Dodwell 1819). Among the commissioned views, quite a few were left out of the subsequent volume but have since become available. One shows within the city walls what is clearly a medieval tower fragment, hitherto unknown to archaeology. It can now be linked into a post-Roman defense wall around this hill, suggesting, together with the ceramic finds at this location achieved through a recent surface survey, that in Crusader times a minor fortified place controlled what was once the main road linking southern and northern Greece.

THE SECOND ERA, late nineteenth century until the late 1950s. With the late nineteenth-century and early twentieth-century recognition of the prehistoric pottery sequences of Greece, the customary "topographic field trip" could now add a prehistoric depth to regional pioneer research and even at times be primarily interested in ascertaining the whereabouts of prehistoric settlements and cemeteries. Regional team research such as that at the British School in Athens, in Laconia (cf. *Annual of the British School at Athens* vols. 12–13 (1906–1907) 15–16 (1909–1910), and 24, 26, 28 (1921, 1925, 1927) and even more clearly on the island of Melos (cf. *Annual of the British School at Athens* vols. 2–5 (1896–1899), *Journal of Hellenic Studies* 17–18 (1897–1898), in its keen interest in every period of the past, in the geography and sociology of each area, shows that catholic intellectual sweep characteristic of a vanishing Victorian scholarship. On the other hand, these were still unsystematic surveys concentrating on known historic locations or "likely" prehistoric locations, combined with rather random travels punctuated by "spot checks" for sites. Villagers might be asked to point to likely settlements.

Also striking was the work of Christos Tsountas (1908), Alan Wace and Maurice Thompson (1912), and Walter Heurtley (1939) in Central and Northern Greece, identifying and refining the pottery from the abundant and easily recognizable settlement mound or prehistoric "tells" that carpet the large plains of Thessaly, Macedonia, and Thrace. On Crete, the distinctive Minoan Bronze Age fabrics and an indefatigable energy in the field allowed John Pendlebury (1939 (1971)), by the opening of World War II, to compile and analyze a remarkable density of sites over many subdivisions from Neolithic to Iron Age. Pendlebury walked the length of the island more than once, but the extraordinary density of mapped sites for sub-phases of the Bronze Age is rather misleading, as they show any location where he observed Minoan sherds, even as few as one (Gkiasta 2008). On Crete, after important German, Italian, and French contributions to this tradition (e.g., by Fritz Schachermeyr 1938), the final flowering came as late as the 1960s with the extensive field trips of Sinclair Hood, Peter Warren, Gerald Cadogan, and Paul Faure into parts of this large island where prehistoric sites were little known or poorly recorded (cf. *Annual of the British School at Athens* vols. 50–63 (1964–1967), and *Bulletin de Correspondance Hellénique* 84 (1960), 86–87 (1962–1963), 89, 91, 93 (1965, 1967, 1969)). Although current approaches will find such work difficult to use, since the countryside is visited rather patchily and randomly, the results have been important in documenting the variety of landscapes used at specific eras (although attention to the post-Roman era was often very limited).

Some of those undertaking extensive field survey were following the German tradition of historical geography, or "Landeskunde." With the outstanding example of Alfred Philippson (1892; Philippson et al. 1950–1959), before them, his students and followers analyzed both the geography of settlement and distribution at particular time periods, as well as the factors underlying the striking changes in settlement location observable over millennia in circumscribed landscapes. Particularly noteworthy are the studies by Herbert Lehmann of the Plain of Argos (Lehmann 1937) and of Eastern

Crete (Lehmann 1939). In the latter example, overall trends for the region were analyzed via a cumulative series of micro-regional natural settlement chambers (Siedlungskammern), in which it was shown that the key resource zones remained the same against a shifting micro-location of settlements. Lehmann's volume on the Argos region is noteworthy in addition for the intellectual breadth of his approach: from raw geology via geomorphology, soils and vegetation, climate, and land use potential, he moves to prehistoric and historic human engagements with the landscape, at times anticipating the social, symbolic, and emotional perspectives which have become only recently popular in landscape archaeology as the "phenomenological approach" (Bintliff 2009).

Regrettably this was the endpoint of extensive work within that nineteenth-century tradition in Continental scholarship, and although a limited amount of similar work continued after the Second World War on Classical Greek settlement patterns, notably by Ernst Kirsten (e.g., 1956), there is little of note on prehistoric human geography till the 1970s. Kirsten's analysis of the Greek polis or Classical city-state utilized many generations of German Landeskunde experience and the patterns of cities across the Aegean to argue that in essence they were essentially not towns in a modern or even medieval sense but rather large villages, coining the term "Dorfstaat" or "village-state" for them. Although his volume is almost entirely neglected, the concept of a small-scale community distribution has not only been usefully employed in the analysis of the origins of settlement hierarchies exposed by survey (Bintliff 1999) but has been mathematically confirmed by a first analysis from Eberhard Ruschenbusch (1985) and since by the major project led by Mogens Herman Hansen on the ancient Greek city-state in the Aegean and throughout the Greek colonial world (Hansen 2004).

THE THIRD ERA, the 1960s to the early 1970s. By the 1960s, we have entered an era of far more detailed regional site survey. A well-defined area is crisscrossed extensively on foot at wide intervals or with a vehicle, and all "likely" locations are investigated together with every previously recorded findspot. The date range and period-by-period extent of prehistoric and historic surface sites are roughly estimated and settlement distributions and site plans published.

One figure stands out for this era in the vast amount of ground he covered, the number of sites he discovered, and the meticulous presentation of survey results, Richard Hope-Simpson. In addition to site prospection in Laconia (cf. *Annual of the British School at Athens* vols. 55–56 (1960–1961) and the Dodecanese (cf. *Annual of the British School at Athens* vols. 57,65,68 (1962, 1970, 1973), often with supporting colleagues, this pioneer spearheaded the massive, 10-year survey of the province of Messenia which became the fundamental source of settlement data for what is now considered to be a classic interdisciplinary investigation into the Late Bronze Age kingdom of Pylos under the direction of Prof. William McDonald. Here for the first time, potential site locations were identified for visits from aerial photographs, which in the special case of Bronze Age fortified hilltop sites was remarkably successful. The Messenia volume (McDonald and Rapp 1972) used the results of some 10-year extensive survey of this large province (3800 km^2) to analyze the settlement, economy, and political organization of a Mycenaean state. Secondary attention was given to the pre-Mycenaean and historic periods in the same region, while the geographical component was broad-sweep rather than detailed at the site level. Created along the lines of major regional projects in Mesopotamia and Mesoamerica, "UMME" demonstrated a whole new battery of research techniques and specialist support. It has changed the nature of Aegean archaeology and set the pattern for all subsequent regional projects. The inclusion of experts in geology, mineralogy, land use, social anthropology, paleobotany, and history set a new pattern for Aegean survey teams to emulate. However, in terms of field survey methodology, the Messenia approach went little beyond the extensive tradition typical of this era. The overall achievements of the Hope-Simpson climax phase of extensive survey as far as prehistory is concerned were summarized in his *A Gazetteer and Atlas of Mycenaean Sites in Greece*, which appeared in 1965 and which was updated with the

assistance of Oliver Dickinson in the form of a *Gazetteer of Aegean civilisation in the Bronze Age* (Crete excluded) in 1979 (Hope-Simpson and Dickinson 1979).

The last-named volume has remained central to all discussions of later Greek prehistory. Its intentional limitation to the Mycenaean mainland and islands was compensated for by using Pendlebury's pre-war (1939, *op.cit.*) compendium of Minoan Bronze Age sites on Crete and David French's impressive extensive surveys of Neolithic and Bronze Age sites in Central and Northwest Greece (French 1967, 1972).

Colin Renfrew, for example, in his magnificent 1972 blockbuster book *The Emergence of Civilisation in the Bronze Age Aegean*, relied heavily on these sources. He compared regional growth curves for Southern Greece and the Islands in known sites from Neolithic to Late Bronze Age times, based on the extensive survey data. Two modes were identified, a straight line demographic growth (Crete and Messenia) (A) and a mode with two growth phases punctuated by a standstill or decline in the Middle Bronze Age (the norm elsewhere) (B).

During the early 1970s, my own research into the relationship between environment and human settlement in later Greek prehistory based itself, for several regions analyzed, on the extensive survey data of Hope-Simpson and his predecessors, including the analysis of landscapes they had surveyed. I also consciously sought to revive the almost defunct historical geography approach of the Philippson School, combining this with the new approach of catchment analysis and other borrowings from locational theory in geography. The influence of the Cambridge Palaeoeconomy movement was at that time introducing the mapping of land potential at varying distances and in varying directions from archaeological settlement sites to suggest locational preferences ("Catchment Analysis," cf. Vita Finzi and Higgs 1970), an approach since commonly applied to the analysis of settlement systems in pre-Modern Greece revealed by survey. I took a series of regional landscapes in Mainland Greece, Crete, and the Cyclades (Bintliff 1977), compiled geology, geomorphology, soil, and land use potential maps for each region, and then studied every recorded prehistoric site in its physical landscape and in relation to its neighbors, employing in the field a detailed catchment approach on a site-by-site basis. Well over 200 sites and their context were thus analyzed, providing a useful database for defining preferences in terms of soils and suggesting the patterns of settlement hierarchy in relation to resources and to territorial space. An approach which focusses on landscapes over time inevitably finds comparative patterns of interest in many phases of human use of the same landscape, especially when influenced by the long-term viewpoint of the German Landeskunde movement, so my regional studies anticipated much later regional survey work by including settlement patterns of the ancient, medieval, and post-medieval periods as comparanda for the prehistoric networks and locations.

THE FOURTH ERA, early 1970s to the early 1980s. However already during my years in the field as a research student, a new survey phase had been inaugurated in Greece, one which I was lucky enough to be involved with through my participation in the "new wave" of Greek survey (a term I invented to mark a critical change in methodology, borrowed from French cinema history). The crucial novelty was the method: intensive, field-by-field survey without preconceptions about favorable site locations. Teams of students led by trained staff walked the land surface at close intervals, 15–30 m apart, to record surface traces of past activity, primarily ceramic sherds.

The source of the intensive survey approach lay in empirical advances in the United States, especially from surveys in its southwest, where it had been shown that increasing spatial cover and time devoted to each square kilometer produced unparalleled new site densities (e.g., Plog et al. 1978).

The results in Greece were predictable: a vastly increased number and variety of sites of all periods were encountered, with a striking proliferation of smaller and less conspicuous sites than were normally encountered in extensive survey. This revolutionary advance was pioneered by Michael Jameson's survey of the South-West Argolid (Jameson et al. 1994) and David

Blackman and Keith Branigan's survey of the Agiopharango Valley in Crete (Blackman and Branigan 1978).

The greater local resolution achievable through intensive survey allowed social archaeology to develop at the local community scale. Thus, in the Agiopharango Valley, the correlation of small Minoan Bronze Age sites with potential cultivable land led to the hypothesis of a social module of several related families sharing the use of a single communal stone tomb (tholos), this monument being placed so as to mark the group's lands and often being associated with dispersed settlement units (Bintliff in Blackman and Branigan 1978 *op.cit.*; Bintliff 1977 *op.cit.*). An analysis of the number of bodies claimed for tombs of this kind elsewhere, applied to the average number of tholoi in use in the Agiopharango, suggested both the number of families per tomb and in total compared favorably with estimates of the potential carrying capacity of the valley soils. In addition, the data and location of rural shrines (several being identified within this valley) were incorporated into a broader theory concerning the mechanisms behind the rise of Minoan palace society, in particular postulating a rural-central place integration via expanding cult systems.

In the light of the vigorous debate in the United States over the selection of survey areas, their size and number, and indeed the whole business of sampling strategies in survey archaeology, it is not surprising to find considerable variability in the exact approach to these problems among the "new wave" of intensive Aegean surveys. The Argolid Survey tackled the region of the southwestern Argolid via a series of manageable blocks, totally surveyed, combined with extensive prospection in the intervening areas. John Cherry's survey strategy for the Cycladic island of Melos involved a 20% sample arranged in staggered transects across the island, each block intensively surveyed (Cherry 1982). In contrast the Boeotia Survey (Bintliff and Snodgrass 1985; Bintliff 2000a) deliberately avoided small survey units and expanded outward in all directions from a modern village, although subsequently smaller landscapes spread widely across the province were surveyed for comparative reasons. Following the Boeotia model was the "expanding core" of the Laconia Survey (Cavanagh et al. 1996, 2002). Further landmark surveys include that of Kea (Cherry et al. 1991); the Atene deme, Attica (Lohmann 1993); Berbati (Wells and Runnels 1996); Methana (Mee and Forbes 1997); Asea (Forsen and Forsen 2003); and the Mesara (Watrous et al. 2004).

THE FIFTH ERA, from the late 1980s. A characteristic innovation of this phase was the mapping of non-site or "offsite" surface pottery, the almost continuous scatter, including post-medieval, medieval, ancient, and prehistoric artefacts, that lies between those peaks of surface debris traditionally defined as "sites." Once again it was further field research in the United States into the "non-site" phenomenon that spearheaded change in Mediterranean survey techniques (Powell and Klesert 1980; Nance 1981). Mapping of artefacts between those concentrations traditionally identified as "sites" (foci of human activity such as settlements, burial areas, sanctuaries, herding shelters, etc.) had revealed a distribution of scattered pieces, from a few score to (most commonly) one or two pieces, which required explanation for their presence in the landscape. This led to a widespread shift within the survey community in Greece and elsewhere in the Mediterranean to taking the individual artefact as the focus of recording, whose distributional patterns led to an analysis of permanent or temporary activity foci as well as "taskscapes" where landscapes of work left visible surface traces. Generally surface finds were quantified using handheld counters, which are now being replaced by GPS-linked (Global Positioning Systems) palmtops.

Part of the "offsite" scatters is known to be due to the presence of vestigial sites, whose surface appearance may well not immediately attract site designation. Moreover sites once discovered can vanish in subsequent seasons, while new sites can emerge in localities previously field-walked and then pronounced to be "siteless" – particularly as a result of shifts in land use across them. It is therefore clear that the distribution of recorded artefact concentrations (sites) in any particular season is only a partial sample of all surviving sites.

Graeme Barker (1984), describing this situation from his Italian survey experience, memorably wrote that small sites "come and go like traffic-lights." To understand the surface sites as a phenomenon, it now became clear that surveys should practice replicable non-site recording on all future Greek surveys, as well as revisiting of areas previously surveyed. The deeper implication is that surface survey cannot expect to recover all the sites that once existed, so that compensation has to be made for those invisible during the study of a region. For demographic reconstructions, this is highly significant, although the fact that smaller and less long-lived sites are mostly those affected by discontinuous appearance, while larger and longer-lived occupational foci tend always to be visible, helps to limit the distortions caused.

It is also appeared likely that land use patterns might be illuminated through the analysis of non-site scatters, where they may include the debris of temporary shelters or areas of manuring (Bintliff and Snodgrass 1988b; Bintliff et al. 2007). Generally historic sources for Greece neglect everyday life in the countryside for larger centers and summary records of population or economic production, so that maps of sites found by survey are not directly relatable to land use. Site locational analysis can give strong indications about land use preferences, but offsite survey adds evidence directly from fields or pastures exploited at particular periods. In Greece as elsewhere in Europe and the Near East, extensive carpets of potsherds can be interpreted as the fossil trace of intensive manuring using household and farmyard waste (organic and inorganic), primarily from villages and towns. The fact that the chronology of such activity is limited to certain periods in each landscape (e.g., the Classical-Hellenistic era in Central Greece) implies special historic conditions stimulating very intensive food production, such as overpopulation, as first argued by Tony Wilkinson in the Near East (Wilkinson1989).

The economic interpretation of sherd carpets did not go unchallenged however. Skeptics suggested that they could be caused by erosion or plowing, for example, spreading sherds outward from sites (cf. Alcock et al. 1994), or even mark the houses of the very poor (Pettegrew 2001). Practical considerations as well as subsequent evidence make such critiques unsustainable, however. Pottery carpets extending for kilometers outward from ancient cities, running uphill and across rivers, can hardly be accounted for through the unintentional disturbance of surface sites, while the very focused surface signal of even the poorest ancient farms and their disturbed finds reaching only a limited distance from their occupational core is clearly distinguishable from the uniform carpet of debris characterizing the sherd carpet phenomenon. As a coup de grâce to objections to ancient manuring carpets, large-scale rural survey in the territory of ancient Tanagra city in Central Greece gave definitive evidence for the sourcing of such carpets from human settlement agglomerations (cf. Bintliff 2012, Plates 11.2a, b). In all directions from the ancient city, dense ceramics littered the fields for up to two kilometers, decreasing in intensity with distance due to the increasing labor needed to haul heavy loads of urban waste. But in the outer territory of the same city, some seven kilometers distant – too far for cost-effective transport of such material – field survey found almost no offsite material between sites, merely recording the small haloes around each site due to its gardens, sheds, graves, and waste dumps.

Finally, similar offsite carpets have now been documented almost ubiquitously in the Mediterranean, while tellingly in Croatia and Spain, the practice of total organic and inorganic waste disposal for field manuring survives in living memory among local farming communities.

The way sites are studied, once identified as anomalous concentrations of finds, has tended to fall into two models since this time. One is a structured sample, where strips, squares, or circles are laid out discretely across the site for density counts and find collection. The other is to grid the entire site and study it as completely as possible. Unfortunately, little experimentation exists to compare the two methods, although what has been done suggests that partial samples, at least where they cover just a minor part of the site surface, are less representative of the periods of

use and the density trends across sites (Bintliff and Snodgrass 1985 *op.cit.*). It appears advisable therefore to follow total study, but a very dense mesh of subsamples, as is used in Todd Whitelaw's very large-scale current Knossos Survey (Whitelaw et al. 2006–2007), may avoid these difficulties.

An important new focus of this phase of Aegean survey evolution was the tackling of large nucleations, including ancient cities, through surface survey (Bintliff and Snodgrass 1988a; Cherry et al. 1991). The city-survey of Thespiai, which required some 100 ha of gridded landscape to complete, took just 2 months to accomplish, requiring some 1000 larger and smaller grid units, although the existence of over 25 periods of occupation and the inherent complexities of unraveling their copresence on the surface have delayed the final publication till 2017 (Bintliff et al. 2017). Perhaps the majority of ancient Greek towns lie in part or whole in agricultural or pastoral land and hence are suitable for surface prospection. While a detailed understanding of house construction or the architectural details of public monuments requires excavation, obtaining a broad understanding of the long-term development of an entire town is feasible through urban surface survey within just a few years of seasonal study. Since the first intensive surveys at Aegean towns were undertaken, analysis of the results has driven a much larger collection of finds to be gathered in more recent urban survey. The city of Koroneia, for example, in Central Greece (around 35 ha), took 6 years of survey to complete (Bintliff et al. 2013), but the comparison with urban excavation is still illuminating: over the same period, some half dozen ancient houses were being excavated at an ancient town in Thessaly.

The practice of urban survey brings serious problems of scale into fieldwork. It remains unclear how large a sample is needed to ensure that each period represented is adequately covered in the collection of finds. The first group of such city surveys in Greece, in the early 1980s, gathered what now seem very small collections: at Koressia on Kea, for example, little more than 100 potsherds were catalogued (Cherry et al. 1991), while at Haliartos in Central Greece, some 700 pieces were collected (cf. Bintliff and Snodgrass 1988a). From the mid- to late 1980s onward, however, it had already become clear that sample size was a big issue in such complex and long-lived sites. Numbers on our Central Greek city surveys went up to 14–16,000 sherds for Hyettos and Thespiai to 40–60,000 for Tanagra and Koroneia. On Crete the current urban survey at Knossos, directed by Todd Whitelaw (op.cit.), has some half a million potsherds collected, but he already has observed that this is inadequate for fine study of the material evidence for each subphase at the long-lived urban site.

Making sense of an urban site requires more than mapping finds of each period as a simple image of city history. The accumulation of buildings naturally buries the oldest levels and privileges the youngest, while some eras such as the Roman Imperial or High Medieval provide hard-wearing and easily recognizable finds compared with others which are more fragmented and hard to date. In some eras, surrounding cemeteries have distinctive ceramics (e.g., the Classical-Hellenistic centuries), but in Roman and especially Late Roman times, pottery deposited in burials is very similar to domestic wares. Urban manuring complicates the surface further, as its density in the city suburbs reaches the levels normally associated with the actual occupation zone further inward. Clearly a multiple approach is needed. Often there have been some localized excavations, including illegal robbing, while in agricultural areas, every year farmers disturb the ground and can reveal structures too. Geophysics and aerial photography often reveal details such as street plans, houses, city walls, monumental burials, and kiln areas, but these methods vary in their success rate on a case-by-case basis, and such "remote sensing" works best for a single period city, since no dating of the features seen can be offered by simply viewing the images alone.

The number of finds available for surface study of Greek cities, if still kept open through farming or grazing, tends to be huge, in the millions for a medium to large town. Thus, the survey collection can only sample a small proportion, but this must

come from a dense grid of sample areas to allow one to see the local changes in size and function of each small area within the town and its suburbs. Generally, a town has a few phases of maximum size and flourishing, and finds of these periods will dominate a collection which focusses on feature pottery (rims, bases, and handles, the most diagnostic fragments). The phases with fewer finds, either because the site shrank to a village or the period involved is very early and hence its material is rarely found on the younger surface of the site, need careful attention. If the Classical Greek finds, for example, are some 10,000 of a city collection, while Early Iron Age pottery makes up a mere 100 or less, we cannot merely take these figures as a surrogate for the level of activity. Firstly, the Iron Age is buried under the historic city so less is coming up from its levels to the surface during plowing and the building of later foundations or because of other ancient and modern disturbances. Secondly, we need to calculate the sample factor, i.e., what proportion of the estimated total pottery on the city surface is being collected. Usually this is far less than 1%, so other things being equal, the true number of Iron Age finds in our imaginary case-study, were we to "hoover" (practice total collection of) the whole site surface, could be well over 10,000.

THE SIXTH ERA, the 1990s to the present. Three major trends typify this latest stage (Bintliff 2000b). Firstly, the appearance of synthetic survey articles and monographs for diverse regions of Greece has encouraged comparison of results (Alcock 1993; Bintliff 1997a; Alcock and Cherry 2004). The aim has been not only to identify methodological issues but also to gain a wider understanding of particular eras of Greek prehistory or history.

Secondly there has been recognized an urgent need to carry out a stricter *Quellenkritik* or source criticism of Aegean survey. Although the enormous flow of results of previous decades provided new and unexpected data, their quality, limitations, and interpretation have raised fundamental questions about methods and how we can create "history" out of them. A series of issues can be mentioned briefly:

(a) It has long been recognized, initially by Jeremy Rutter (1983), that some periods of the past have less well-preserved and/or recognizable surface ceramics. Moreover, most Greek sites are multiperiod, where earlier levels are less likely to be plentiful on the surface. I have suggested for Mainland Greece, for example, that much of the prehistoric record is a "hidden landscape" (Bintliff et al. 1999) where small scatters of finds may be all that is left of richer settlements or even be undetected in intensive surveys. The Iron Age, Archaic, and Early Byzantine eras may suffer similar discrimination. Special methods must be applied to tackle such situations.

(b) The rise of offsite survey in the preceding era did not curiously lead to a systematic publication and analysis of finds outside sites. A linked problem is the evidence that settlements themselves seem to consist of occupational cores and haloes of peripheral finds (rubbish dumps, smears of finds pushed out of sites by the weather and plowing, kitchen gardens, graves, craft areas, etc.), so that estimates of site size and by implication human populations vary considerably on the basis of where to place an assumed "site edge." As we have seen, analysis of the inter-site taskscape finds moreover became bogged down into a, for long, unresolved dispute on the existence of manuring scatters in the wider landscape (cf. Alcock et al. 1994, with Snodgrass 1994), often discouraging treatment of offsite densities at all. The present writer hopes that the exhaustive treatment of all these problems in the survey monograph *Testing the Hinterland* (Bintliff et al. 2007) has clarified the situation.

(c) An important corollary of the inclusion of offsite finds into the analysis of sites is the need to ensure that material found, for example, on a rural farm actually belongs to the period when it saw occupation. Let us take the case of a landscape with much urban or village manuring in period A. A certain field received a significant scatter of ceramics from one of these nearby agglomerations. In period B, a farm is established on the same field. The survey archaeologist recovers material of

periods A and B, and perhaps that of A is enough to suggest occupation in both periods. A solution to this problem is to record the offsite finds in sufficient detail so that one can summarize the density of finds of any period in the district of the site. To support site use in any period, then, it would be necessary to show that the density of finds was clearly elevated over that which can be found in fields in the general area of the site. It is however also necessary during this procedure, which is called residual analysis, to identify from overall ceramic densities out from the site core its "halo area," i.e., a zone impacted by the site occupants through local rubbish disposal, sheds and yards, kitchen gardens, and burial and minor industrial areas. Beyond the site core and halo, we average sherd densities per period in the further landscape and use these as a control over what has been picked up at the site (see Bintliff and Howard 2004 for applications of this method).

(d) An issue that is becoming central to the current active survey community is the conducting of experiments to examine the effects of varying methods of fieldwork and analysis. New projects tend to follow older ones rather arbitrarily without there being a firm basis of experimental data to judge the advantages and disadvantages of the chosen techniques. It is not clear how much material needs to be collected to form a representative assemblage of finds from a site, surprising since it should be clear that the number of periods found there and the size of the site naturally raise such issues. City surveys can be analyzed on the basis of anything from a couple of hundred to tens of thousands of sherds, depending on the decision of the project leaders. In preparation for the publication of the city of Thespiai survey, we recently calculated that some 600 sherds for *each period* of a large multiperiod site would be needed to ensure a realistic map of activity foci per phase (Bintliff 2014). It is necessary to aim for the "cultural biography" of each site, however small, where intensive field study and analysis of finds should be complex enough to reveal the often very different ways each location has been used in the long term. Such an exercise reveals that most multiperiod surface sites undergo considerable changes in their size and function (cf. *Testing the Hinterland* op.cit.). However, to achieve such an approach requires the collection of significant assemblages of finds as well as their detailed mapping across the site.

(e) A more penetrating approach to survey is being immensely aided by the advent of new technical aids. Geographical Information Systems (GIS) speed up and make far more accurate the laying out of fieldwalking units in the landscape and across sites, while handheld computers can record both study units and their contents in real time. Differential GPS devices allow highly accurate location of both sites and surface objects in all three dimensions, while laser recording can provide images of standing ruins or field sections (road or stream cuttings, etc.). The study of the "phenomenology of landscape," whether that means practical matters of estimating how people moved around the landscape or investigating more emotional issues of human perception of space, can be speedily estimated through GIS. Considered a surface technology but, in reality, a subsurface one, the increasing use of geophysical methods offers a nondestructive way of looking beneath the surface finds into the complexity of the underlying built environment. Results can be both spectacularly illuminating (where, e.g., the entire street and house-block plan of an ancient city is revealed; cf. Music et al. 2008) and be a failure, being highly dependent on geology, soil conditions, climate, and the type of built environment being examined.

(f) The relatively poor recovery of remote prehistoric sites even through intensive survey, by which we mean Paleolithic and Mesolithic hunter-gatherer sites, has encouraged specific adaptations to field techniques. Curtis Runnels has used predictive modelling to identify locations most favorable for hunter-gatherer activities and then focused research in such small districts, with remarkable success (e.g.,

Runnels et al. 2005). New field projects in presently marginal landscapes such as the high uplands of Greece have also discovered a far greater density of prehistoric sites where later burial, erosion, or human activities have not been active in concealing or destroying their traces (Efstratiou et al. 2006).

(g) In the extensive and early intensive survey decades, ceramic and lithic collections were primarily made to provide chronology for a site. Key artefacts which could be linked to published finds from excavations were central. This meant, for ceramics, that locally produced cooking wares and everyday domestic wares were neglected. With the recognition that larger assemblages should be gathered to offer more information on social and economic questions, came a shift to the creation of regional finds' collections to form a reference base for analysis. A modern survey will accumulate such a reference collection of local and imported ware types and shapes for all periods, constantly updating it as new types come to light, especially specifically local forms. Fabric analysis has become a major area of advance here, using visual inspection but also tools like portable XRF machines and digital microscopes, to identify distinctive ceramic fabrics. It is often possible to recognize a pottery fabric distinctive for a local area of production, so that body sherds (the commonest fragment in survey) can be given a provenance, and even at times date, if the fabric has a confined use in time. It seems now likely from such work that most cities in Greco-Roman antiquity made the majority of their own pottery.

(h) If a project has a full reference collection of local and exotic types and fabrics, it is now feasible to track the degree to which any urban, village, or farm site participated in ceramic trade at varying distances. In the case of the Roman Imperial period, for example, tableware and storage amphorae can appear in the countryside from the region, the wider Aegean, the Eastern Mediterranean and Black Sea, and even Tunisia. An ongoing research field maps imports as they are found across the landscape surveyed, showing that some towns in Greece were far more integrated into interregional commerce than others (Peeters et al. in press). Additionally, and in the hinterland of such towns, we can also see that rural sites vary considerably in the degree of their participation in the market. Here survey can offer exciting new evidence for the economic history of Greece in all periods.

The third major theme in the last generation of field survey has been a far greater investment in the landscape history of the post-Roman periods and the medieval and postmedieval eras of Greece. Increasing success in identifying typical ceramics of subperiods of 1–200 years' duration within these eras has allowed integration with historical sources. Moreover, there exist many thousands of deserted villages and installations such as waterworks, roads, and churches which offer documentation of the built environment in connection with often abundant surface artefact finds (Lock and Sanders 1996; Bintliff 2000c, 2012; Sigalos 2004; Davies and Davis 2007; Vionis 2008; Bintliff and Stoeger 2009).

Central Topics Where Survey Has Contributed to Greek Prehistory and History

Survey may once have been the means to "put dots onto maps," so as to provide a view of settlement change in Greece over time, but now it clearly wishes to offer insights into past social, economic, and cultural systems. We might suggest a series of examples from diverse periods to illustrate how surface prospection is deeply involved with the wider reconstruction of the Greek past.

The Bronze Age

The blanket term Minoan-Mycenaean civilization has long offered the impression of a uniform landscape with high levels of population living within a shared political framework of hierarchical palace-states. Survey has allowed us to critique

this picture, both extensive and intensive, and confirmed Oliver Dickinson's proposal (1982) that these landscapes were far more varied one to another: some are indeed high density and others well below the level of local food sustainability (the "carrying capacity" in ecological terms). This can tie in with another suggestion that palatial states may have formed only one mode of organization of those societies sharing Minoan or Mycenaean cultural forms. In regions well away from the great palace centers, chieftain or "big man" social organization could have prevailed.

The growing density of survey projects allows provisional estimates of population variation across Greece at particular phases of the Bronze Age. Thus, a recent analysis (Bintliff in press) suggests that the mature Minoan civilization on Crete was dangerously close to maximum population for the island's resources, while Mycenaean Messenia was comfortably below its human carrying capacity. The Argos region with its cluster of towns was not so sustainable a society unless it could rely on controlling the surplus food from its hilly hinterlands and the adjacent region of the Corinthia.

The Classical-Hellenistic Greek Period

Survey has been especially successful at revealing the forms of rural life which are only indirectly portrayed in ancient Greek texts. In particular on the Southern Mainland and Aegean Islands, a prominent phenomenon is a modest to medium-sized estate center, mostly less than 1 ha, often referred to as a "family farm." Their ubiquity has surprised some ancient historians, who envisaged farmers as based in cities and villages, and indeed in Greece such small-scale dispersed estate centers have been extremely rare over the millennia covered by survey. Some doubt was raised initially as to whether these farms were permanently occupied or merely used seasonally, but the majority reveals artefacts indicating a broad-based residence (weaving equipment, associated graves, tablewares, large storage vessels, etc.). A minority which has very limited types of ceramics may well help us identify seasonal agricultural bases in the countryside. In one survey, that of the deme of Atene in Attica, no village center has been found, so that here all occupation must have been in dispersed estate centers in the Classical Greek era (Lohmann 1993). Nonetheless, further reflection has added a more nuanced reading of these rural sites. Urban survey has indicated (Bintliff 1997b), and this is confirmed by the Polis Project of Mogens Hansen (2004), that some 70–80% of population in Classical-Hellenistic times lived in the cities, which were typically only 1 hour or so from their territorial borders, so that only a minority of citizens dwelt in the countryside proper; the majority (who were farmers) therefore commuted daily to their fields. This raises the interesting suggestion that family farms represent a desire to maximize estate production for some families, especially important since in many city-states, maintaining a healthy size of farm was a requirement for full participation in the affairs of the city.

In Messenia, dominated by Sparta in Classical times, its inhabitants reduced to serf status, survey shows in contrast a general absence of family farms till after Sparta lost its grip on the province (Davis 1998). It seems likely that the oppressive form of land use inhibited the kind of investment in the landscape seen in more democratic regimes.

The Roman Era

Ancient authors (e.g., Polybius, Strabo), portray Greece under Rome often in very negative terms, suggesting depopulation of town and country in many regions, although the religious centers are still thriving. Historians were very skeptical of these images, considering them as a "topos" or literary convention, designed to explain how the Greek city-states and kingdoms fell under Roman rule. Survey has shown very clearly that over much of Greece, there was indeed a dramatic depopulation of the countryside in the last two centuries BC, while many towns were abandoned or shrank. At the same time, survey has demonstrated that a few regions entered a new expansion of town and country, such as at the Roman colony of Patras and in its hinterland in Achaia. Such discoveries allow us to get closer to the varied ways in which the expansion of Roman power and its more commercial economy

transformed the Aegean world (Bintliff 2013a). The replacement in the landscape of the Classical family farm by larger villa-type establishments, also well-evidenced by survey, reinforces the picture of a dramatic period of change for Greek society.

Late Antiquity

If survey has caused significant modifications to accepted views in prehistory and Greco-Roman times, its impact for Late Antiquity (for Greece ca. 400–650 CE) has been even more notable. "The Fall of the Roman Empire" has been expected to have been accompanied by universal decline throughout the provinces, Greece included. For those more familiar with the divergent trajectory of its Eastern half however (the Eastern Roman Empire), our ancient sources make clear that, centered on Constantinople, a powerful if weakened state survived major attacks from hostile powers till the early seventh century CE. The reality which has emerged from numerous surveys throughout the Aegean goes further, in showing that the frequent decline in town and country associated with the Early Roman Empire is reversed in the rural world at least, where a revival of settlement is visible, particularly associated with enlarged numbers and sizes of villas and associated villages. The fate of towns however shows a different story: most remain at their reduced size of earlier centuries or disappear. A powerful explanation for the more positive picture of the Eastern Empire compared to the Western provinces after the fourth century CE is the reorientation of the Roman world to the new capital at Constantinople and the stimulus this gave to the landscapes supplying its huge population and the more resilient standing army on its eastern borders (Abadie-Raynal 1989).

Nonetheless, survey is proud of its reputation for almost annual reconsideration of its methods and theories, and this model has not been without critique from within the survey practitioner field. David Pettegrew (2007) has argued persuasively that the extraordinarily high recognizability of Late Antique ceramics, and in particular the fact that often some 50% of surface assemblages of this phase consist of innumerable fragments of large diagnostic transport amphorae, has led to a major exaggeration of the "busyness" of the contemporary sites and landscapes, compared to preceding periods. In Central Greece moreover, large villa sites seem to show much storage evidence from surface collections but limited evidence for large resident domestic populations, suggesting that these estates were little populated, with their labor force coming from associated village sites and the shrunken towns (Bintliff et al. 2007). Nonetheless, a significant revival compared to the Early Empire, in the rural world at least, is incontestable, even if the emphasis on larger villa estates supplying a vibrant interregional commercial market is a fragile specialization which will not survive the near-breakdown of trade in the later seventh to eighth centuries.

Medieval Rural Life

As with Classical Greece, our understanding of the Greek countryside between 700 and 1400 CE has for long depended on quite limited references in Byzantine and Frankish Crusader sources, with occasional spotlight windows provided by a small number of late Byzantine records of villages and estates owned by monasteries (especially those on Mount Athos) (Laiou-Thomadakis 1977). The growing interest in long-term landscape archaeology within the surface survey community in Greece from the start of the intensive prospection phase was at first hindered by the lack of specialists in the ceramics of this long era, so that sites were at first merely dated to the "medieval," or "Byzantine" or just "post-Roman" periods. The wares which were datable were those fine tablewares suitable for museum display rather than the bulk of finds which were roof tiles, domestic, and cooking wares. A breakthrough occurred through the involvement of one unique scholar, John Hayes, whose ability to work with all classes of pottery from the geometric to the early twentieth century CE revolutionized surveys in Greece within which he was active from the later 1980s onward. A deserted village was no longer "medieval" or "postmedieval" but could now be shown to be twelfth to fourteenth or seventeenth to eighteenth century CE. Younger followers of his work

now expanded the regions where such detailed historical archaeology could be reconstructed, such as Guy Sanders, Athanasios Vionis, Effie Athanassopoulos, Pamela Armstrong, and Joanita Vroom (cf. Sanders 2000; Vionis 2012; Athanassopoulos 2010; Armstrong 2002; Vroom 2003).

The focus on villages was due to a general fact of post-Roman Greece: towns declined dramatically in number and often survive today and so are accessible to limited excavation but not usually urban survey, while in their place came a landscape of villages (farm sites became rare and a regional element). It soon was clear with the new refined chronology that the villages of the period 700–1400 CE were often confined to certain periods of use, before most became permanently abandoned; especially a great rise in their number from ca. 1000 CE was followed by a florescence till a massive abandonment during the fourteenth century. This sequence could be related well to the rise and climax of the Byzantine Empire, but surprisingly the conquest and subdivision of Greece by the Fourth Crusade and the imposition of a Western European feudal economy did not cause any visible effects on the prosperous village landscapes established already. An exception to this generalization is the occasional localized displacement of an existing Byzantine peasant settlement to a more defensible position beside or inside a new Crusader fortification, as at Mount Tsaliko in the Peloponnese (Gregory 1996) or at the deserted village of Palaiopanagia in Central Greece (Bintliff 2012, chapter 19).

Survey archaeologists working in this period were emboldened by the large number of such DMVS (deserted medieval villages) discovered in their regions and the plentiful surface finds they provided, to look at the commercial links of such communities and their social and economic structures, taking their lead from the much longer established tradition of DMV research in Western Europe. Most recently, the evidence of air photographs and mapping of field systems has allowed survey archaeologists to associated particular field systems to medieval settlements (Crow et al. 2011).

The Ottoman Era

If medieval archaeology in Greece had always at least a basis in the tradition of Byzantine architecture and art history, as well as archival history, the same could not be said of the subsequent lengthy era of Ottoman Turkish rule in Greece (fourteenth to nineteenth centuries CE). The extremely negative image of the Ottoman centuries common in Greek historical studies, deriving chiefly from the era of general decline in the late eighteenth- and early nineteenth-century Empire, had never inspired a community of archaeologists to devote themselves to its surviving remains in town and country (with a few notable exceptions, cf. Bintliff 2012, chapters 20 and 21). Once again it would be the result of the neutral, long-term approach to landscape archaeology typical of intensive survey projects in Greece that changed the situation permanently. Based on the inspiration of John Hayes, numerous rural sites, mostly villages or hamlets, discovered by regional projects, could be assigned their place in subdivisions of Early, Middle and Late Ottoman, allowing a picture of the changing settled rural landscapes of Greece to be built up.

If Byzantine and Frankish Greece have only scanty archival and historical texts to link to rural life, a fortunate association with a notable Ottoman historian, Machiel Kiel, opened up a perspective undreamt of by survey specialists. The Ottoman Imperial archives, especially in the grand centuries of the Empire (ca. 1400–1600), were very detailed at the village level, listing population, crop and animal production, and additional information on associated monasteries, mills, and fairs (Kiel 1997). Once a deserted village could be given a name to be found in the regional tax registers (in Central Greece, some 70–80% could be linked in this way, Bintliff 1995), survey archaeologists were able to compare the statistics to the site size, date range, and ceramic finds from the village's survey.

This confirmed the previously often disputed claim of Ottoman specialists that the Early Empire, under the "Pax Ottomanica," was a long period of rapid population growth and a flourishing economy in Greece. The subsequent gradual decline of the countryside through the seventeenth to early eighteenth centuries attested

by historical and archival sources was also clearly revealed by the disappearance or shrinkage of villages. At this point, a new discovery added depth to the work of survey: village sites still active in the Middle to Late Ottoman centuries often contained the visible remains of houses, of types well-known to Greek Folklore and Vernacular Architecture specialists from the post-Ottoman era (Philippides 1983–1990). A natural extension then led to the recording of such houses and a new interest in traditional houses which was taken into the package of survey approaches for the last and final era, the Early Modern period (nineteenth to twenty-first centuries CE). A major program recording the fast vanishing traditional domestic houses of the Peloponnese grew out of the Minnesota Messenia Project and the work of its architect Fred Cooper (Cooper 2002), while in Central Greece, houses have been recorded as part of the ongoing Boeotia Project both from deserted villages (beginning with examples from the fourteenth century CE) and existing rural settlements (cf. Bintliff 2012, chapters. 21–22), and arising from this work, a general synthesis was published by Sigalos for the whole of Greece 2004.

In a very recent development, Athanasios Vionis made use of the combination of survey ceramics, Ottoman tax records, and house remains from two deserted villages in Central Greece to contrast the economic strategy, wealth, and relationship to wider economic links of two contemporary Ottoman era villages (Vionis 2016).

Early Modern Landscape Archaeology

It might seem that the period ca. 1800 to today would be well-known enough to prevent survey archaeology from adding new evidence to the narrative, but since postmedieval archaeology is still in its infancy in Greece, surface prospection has been a leading sector in this period for some 20 years. The emphasis has been again on the rural world, since the troubled young Greek state saw many new village abandonments and displacements, offering a large number of DMVs for surface study, mostly now providing standing building remains for recording of lifestyles. The paintings and sketches of the Western European Travellers of such communities were replaced by photographs by the end of the nineteenth century, accompanied by descriptions of village life continuing up till the presentday, recorded memories of the oldest inhabitants of surviving modern communities. Survey can add significant extra features: the types of pottery indicate levels of wealth, eating habits, and the degree to which a rural community is interacting with the wider world through commerce and fashion. Moreover, the clear continuity which can be made to current rural society allows a way for regional projects to show their involvement in creating a vivid sense of local heritage for the communities they work within (see further below).

Future Directions

I suspect that the current source-critical phase, coupled with advances in digital data collection, recording, and analysis, will make much clearer how we can reach stronger conclusions on the nature and history of surface sites and the evidence of human activities in the surrounding taskscapes. This will offer historians greater confidence in combining survey results with their own textual reconstructions of dynamic landscapes and townscapes. It seems necessary to propose to future surveys that they cover large contiguous areas, quantify surface finds both off- and onsites, collect large samples of both of the latter environments, and conduct experiments with different field techniques. Improvements in the resolution of ceramic study through moving from diagnostic wares dated by excavations elsewhere, to classification following a local fabric series, will allow local assemblages to be identified more appropriate to the district under study, as well as bringing to light contrasts between local production and imports.

Comparative studies of survey results should increase so that localized scenarios can be compared with the wider picture of a particular era of the past. A neglected theme here is long-term comparison: can we compare population and land use levels at different phases of occupation of the same landscape, and what are the

implications of such an analysis (cf. Bintliff 2005 for Boeotia)?

It cannot be stressed enough that current archaeological research in Europe and the wider Mediterranean has turned away from large-scale excavation in order to focus on sites which are under threat of destruction from engineering works, house and hotel construction, and intensive agriculture. This means that the vast majority of prehistoric and ancient to pre-modern sites will not be researched by invasive procedures. It is here that the non-destructive approach of surface prospection will be playing an ever more vital role, including surface artefact survey, geophysics, and air photography. This is relevant especially for Greece, where almost every village and even field have traces of past human activity waiting to be recorded.

This leads us to a final theme for future development, a closer involvement of local communities in landscape research. Greece is a country with an especially famous Classical past, preceded by the earliest civilizations in Europe with the Cycladic, Minoan, and Mycenaean societies. Subsequent post-Roman periods are slowly becoming better-known with the results of numerous field surveys which intentionally aim to reveal the long-term history of the landscape. Yet knowledge of this multimillennial story, concluding with the contemporary towns and villages, is exceedingly poorly integrated into the educational program of Greek schools and universities. The rural population finds very little to attach the story of their own landscape and settlement to, when the focus remains on Classical Athens and the Panhellenic sanctuaries. Thus, they seek their own "place in history" through identifying monuments, usually of recent age, sometimes much older, which reflect the involvement of their ancestors in great events such as the Greek War of Independence or even imaginary events such as a visit to their community by notable historic figures such as Alexander the Great or the Ottoman Sultan Suleyman the Magnificent (Forbes 2009; Bintliff 2013b). The mayor of the village of Aghios Georgios in Central Greece, for example, aware that the ancient city of Koroneia lay in village territory, wished to make a monumental connection to the Classical heritage of his community by building a replica, at the entry to his village of the one very visible standing monument at the ancient city site – a tower. Sadly, it lies outside the ancient town and represents the remains of a Crusader feudal tower, the mark on the landscape of an alien power from the thirteenth century CE.

Survey projects will need to engage with local society to make their knowledge of landscape history accessible to the people who live and work there today and across whose fields they walk. Excavations in Greece still focus on the Greco-Roman and prehistoric eras, remote in time and connection to modern communities. Survey has the particular advantage that it gives equal attention to the medieval and postmedieval centuries during which contemporary settlements generally came into being or took their present form and hence is uniquely in a position to situate local towns and villages into a reliable local historical perspective. Moreover, as the Greek state, through its public archaeological service, is usually unable to fund research into locations not at risk from imminent destruction, it is local communities who may need to take greater responsibility for protecting sites and monuments in their territory, especially the remains of structures and infrastructure of the recent centuries (examples of traditional houses, water management systems, etc.). Transferring the results of intensive survey into local history, made easily available to the relevant local groups, seems an urgent task and perhaps even more important than contributing to academic knowledge accumulation.

Survey Archaeology in the Roman World

Alessandro Launaro
Faculty of Classics, University of Cambridge, Cambridge, UK

Introduction

A considerable feature of Roman civilization was the creation and support of a dense network of urban settlements. In this respect, the case of Italy is even more remarkable if one considers that – besides the presence of a megalopolis like Rome (with its one million inhabitants) – there existed about 430 urban centers scattered all over the peninsula. The thousands of cities and towns of the Roman Empire were connected and supplied

by a much-celebrated and highly effective infrastructure made up of ports, roads, and aqueducts. More crucially, each urban polity possessed a well-defined territory (ager): it was (in part) laid out as a regular grid network of squared cadastral plots (*centuriatio*), and it was specifically meant to provide the inhabitants with most of the resources they needed (e.g., foodstuffs, raw materials). Preindustrial urban populations always required a comparatively higher rural counterpart to support them, and in this regard, the highly urbanized Roman world was no exception. That is precisely why a large number of farmsteads and villages populated the countryside and took active part in the social and economic life of nearby towns (De Haas and Tol 2017).

This balanced account, however reasonable it might sound, is actually a rather recent achievement. Whereas the archaeological remains of Roman towns, roads, and aqueducts have for long been – and in many places still are – a prominent feature of the landscape, most traces of rural occupation have gradually faded away or disappeared altogether. Indeed, unlike more imposing stone or brickwork buildings, most rural houses were simpler structures, often made from perishable materials (e.g., half-timbered wattlework known as *opus craticium*). If it were not for the occasional remains of monumental villas, one would be left to wonder whether the Roman countryside was settled at all. Textual evidence could not be expected to fill such a gap and, in general, generations of scholars became persuaded that the "Graeco-Roman world was a world of cites" where the "agrarian population, always a majority, most often lived in communities of some kind, hamlets, villages, towns, not in isolated farm homesteads" (Finley 1977: 305).

This would be still the dominant view if it were not for a combination of largely unrelated events that took place following the end of the Second World War (see section "Historical Background"). For the very first time, those meager archaeological traces of ancient rural settlements were surveyed and identified as such. A systematic approach gradually developed, and survey archaeology has since provided incontrovertible evidence as to the impressive scale of rural occupation and to the vitality of the ancient Mediterranean landscape (hence it being often referred to as "landscape archaeology"). Given the strong bonds between human settlement and its environmental context, this discipline could have not but embraced a marked holistic attitude and therefore exhibited, since quite early on, a very strong interdisciplinary character. In this way, survey archaeology has not just widened our understanding of the Roman world, it has profoundly transformed the way we look at it.

Definition

Survey archaeology is a (sub)discipline which is primarily concerned with the record, analysis, and interpretation of material remains pertaining to past human settlement patterns across *both* rural and urban landscapes (Johnson and Millett 2013). It relies on a body of techniques that include fieldwalking, aerial survey, and geophysical prospection. It also benefits from its close connection with the environmental sciences (e.g., geoarchaeology, archaeobotany) and further integrates the spatial analysis potential of modern geographic information systems (GIS). When engaged with Roman landscapes, it avails itself of the sheer amount of contextual information which is often available in the form of ancient documents (e.g., literary works, inscriptions, *itineraria*/road maps), later historical accounts (e.g., reporting features that were then visible but are no more), and modern place-names (e.g., often reminiscent of an ancient origin).

Fieldwalking (or field survey) is certainly the cornerstone of survey archaeology everywhere. It requires a group of surveyors to walk across a field in parallel lines set at a regular distance from each other and to look for archaeological materials laying on its surface (Fig. 1). It is based on the awareness that such materials are spread all over the landscape and that artifact density varies in relation to the intensity of past human occupation.

Although there are several depositional and post-depositional processes involved, this is a phenomenon which is primarily related to the

Survey Archaeology in the Roman World, Fig. 1 Systematic fieldwalking in Central Italy

Survey Archaeology in the Roman World, Fig. 2 A dense plowsoil assemblage over a freshly plowed field in Central Italy

spread of mechanized agriculture: by reaching deep soil layers (up to 1.5 m), modern plows have disturbed or truncated otherwise sealed archaeological contexts, turning them upside down and therefore making them visible on surface (Haselgrove 1985). This "plowsoil assemblage" (Fig. 2) does indeed provide a sample what is buried below and when the density of material is especially notable – whether in absolute terms or relative to the surrounding context – they are taken to signal the presence of a site (i.e., a proper settlement). Of course, the visibility and potential for recovery of a site are hugely affected by the nature of the material culture originally associated with it and left over when it was abandoned (in terms of both quantity and quality). From this point of view, the Roman period is exceptionally well attested, thanks to its everyday use of pottery and the widespread employment of bricks/tiles in buildings (once fired, clay becomes extremely resistant to decay). Roman finewares are an especially relevant case. Besides their relatively sturdy quality and vast distribution network, their shiny gloss colors (black, red, and orange) have made them extremely visible in the plowsoil and relatively easy to recognize as such (Fig. 3). Furthermore, because such features are specific to well-dated productions (Republican black gloss, early Imperial terra sigillata, and mid-/late Imperial African red slip), even heavily eroded sherds do present a significant dating potential. This chronological pattern is mirrored

Survey Archaeology in the Roman World, Fig. 3 Color comparison of potsherds of black gloss (black), terra sigillata (red), and African red slip (orange)

by specific types of amphorae and all these elements taken together help to explain why most surveys have adopted a Roman periodization that is broadly the same (Republican, early Imperial, and mid/late Imperial) (Launaro 2011: 85–87).

Aerial photography (vertical or oblique) has provided another hugely impressive contribution to our understanding of the Roman landscape. Indeed, more or less substantial buried features can turn out pretty neat from above if the right conditions are met (e.g., crop marks), even though general practice seems to favor some degree of verification in the form of aimed fieldwalking. Among the more recent remote sensing techniques (e.g., processing of satellite imagery), LIDAR (Light Detection and Ranging) is certainly adding a further level to aerial survey as it allows the identification of barely perceptible surface variations over extensive areas (e.g., structures or earthworks of various kinds, even obscured by the cover of deep vegetation). In general, traces of Roman field systems (as still preserved/marked by secondary roads, boundaries, and ditches) are especially recognizable, thanks to their regular grid pattern and consistent (Roman) measures. Remarkable work has been carried out which has combined aerial photographs, cartography, and the original prescriptions of the Roman land surveyors (*Corpus Agrimensorum Romanorum*) to identify large tracts of the landscape wherein centuriation is still preserved (e.g., Chouquer et al. 1987).

Geophysical survey is another approach which is now widely employed – and with outstanding results, especially when combined with fieldwalking (e.g., Keay et al. 2000; Johnson and Millett 2013). A suite of available remote sensing techniques (e.g., georadar, magnetometry, resistivity testing) that aim to identify notable variations in the physical qualities of the (sub)soil. In this respect, structural remains will often stand in stark contrast to the context they are buried within, and once mapped, they are likely to provide a draft plan of the site. More specifically, magnetometry has proved a very favored choice across Roman archaeology as it allows a cost-effective prospection of extensive/complex sites and it is especially suited to detect brickwork (strong magnetic signature), from which many Roman buildings were built. It is often paired with on-site fieldwalking and test excavation.

Survey projects usually aim at reconstructing the long-term settlement history of a given landscape (Cherry 1983). As such they adopt a diachronic approach, cutting across several periods of human prehistory/history and thus requiring the collaboration of several experts from different fields. Study areas are usually defined as well-bounded and self-contained environmental regions (e.g., a river valley, an inland basin), the main objective being to recover, analyze, and interpret the way different human societies have engaged with a consistent landscape over time, thus highlighting long-term constants (similarities) and period-specific variables (differences). Although this diachronic approach is duly observed in terms of data collection and analysis, research design tends to make some periods more prominent as a result of the interests – and expertise – of the individual scholars involved. This is especially evident when the study area is instead defined according to period-specific political boundaries

(e.g., the territory (*ager*) of a Roman town) or when survey is meant to provide a wider context to a prominent site (e.g., the neighborhood of a villa). A case apart is represented by those projects that are launched by local or national institutions in order to improve knowledge, preservation, and management of the cultural heritage within their own territorial jurisdiction (e.g., official archaeological maps). As such, they employ modern administrative boundaries that might bear little or no relationship with both environmental units and ancient territories, while (in principle) they are less inclined to favor one period over the others. Broadly speaking, however, the majority of surveys across the Mediterranean basin – whatever their stated goals – show the tendency to be primarily focused on the Classical period, with further emphasis on either the Greek phase (in the East) or the Roman one (in the West).

Historical Background

The origins of survey archaeology in the Roman world lay in a long tradition of studies concerned with the landscapes of Roman Italy. As such they developed out of the Italian humanism of the late fourteenth century (early Renaissance): indeed, with the rediscovery and philological reappraisal of Greek and Latin literature, there came an interest in the sites and places that had been mentioned by ancient authors. This prompted early scholars like Flavio Biondo (1392–1463) to research the ancient topography of Rome and the historical geography of Italy. By their very nature, these approaches were heavily informed by textual evidence and therefore primarily biased toward those features which arose more prominently as the setting of ancient narratives: Rome and the other named cities, together with the main roads which connected them. Such an interest further developed into the early modern era (well into the nineteenth century) as local antiquarians and learned travelers from the Grand Tour strove to explore suburban landscapes in search of ancient monumental remains. By this time the "landscape with ruins" had gained much popularity (e.g., in paintings) and, therefore, such early "surveyors" were primarily attracted in their wanderings by the most prominent (i.e., visible) sites, where standing structures could be actually observed (e.g., necropoleis, mausoleums, aqueducts, rural sanctuaries, or major rural villas). By the late nineteenth century, this attitude had evolved into "ancient topography," a more structured enquiry which involved a thorough documentation (e.g., mapping, survey) and a systematic analysis of monumental remains (Potter and Stoddart 2001: 4–10). Nonetheless, the resulting picture was still biased toward urban spaces. The rural landscape – set aside as the idyllic setting of so many works of poetry – was then perceived as nothing more than the territorial extension of primarily urban communities, whose population worked the land by commuting everyday between town and country. This is hardly surprising given the fact that these earlier studies were still strongly inspired by and rooted in ancient literary accounts – from which they also derived the very same urban elite bias.

Things were about to change with the end of the Second World War (Potter and Stoddart 2001: 10–16). During the conflict, the Royal Air Force had extensively photographed large tracts of Italy from above in order to monitor military activities and targets. This marked the first large-scale introduction of aerial photography in the archaeology of Italy as hundreds of previously unnoticed features in the landscape were discovered and recorded. Furthermore, following the war, a strong process of extensive urbanization invaded the suburban areas of most Italian cities, especially Rome. This brought about an impressive alteration of the landscape together with an equally impressive destruction of still-standing archaeological remains, the very same remains that had been the focus of earlier topographic surveys. Aware of this critical situation, John Bryan Ward-Perkins (1912–1981), the director of the British School at Rome at the time, launched teams of surveyors across South Etruria (hence the much-celebrated "South Etruria Survey") to record as much archaeological evidence as possible, before it was too late. This took place at the same time as the first large-scale introduction of mechanical heavy plowing (see section "Definition"), and it did not take much time before

these early surveyors noticed how such an impressive destruction had the unexpected result of bringing to the surface a vast array of buried archaeology which otherwise would have gone completely undetected, especially as it pertained to small rural sites. Although lacking the imposing structural remains which signaled the presence of major sites (e.g., rural villas), such smaller occurrences were made prominent by the quantity of archaeological materials (e.g., potsherds, fragments of tiles and bricks). This plowsoil assemblage signaled thousands of sites across the landscape, often interpreted as evidence of farms and, therefore, of an extensive rural population (i.e., settled in the countryside).

The South Etruria Survey did contribute to a "revolution" in landscape studies as a new, formal methodology was eventually developed and introduced all across the Mediterranean region, aimed at a systematic archaeological survey of plowed fields. Rapidly, it also became clear that an exclusively urban-oriented understanding of the rural landscape was misleading and that these rural settlement patterns had to be understood in their own (environmental) setting. This opened the way to the integration of a specific expertise devoted to environmental reconstruction (e.g., geomorphology) and affirmed landscape archaeology as a fundamentally interdisciplinary endeavor (see section "Definition"). Research on Roman landscapes has since benefitted overall from such attitudes as more and more projects have followed – in Italy and beyond (Barker and Lloyd 1991; Potter and Stoddart 2001: 16–23). This has called for a more balanced understanding of the complex relationship between town and country and has warned scholars against the indiscriminate use of just one set of potentially biased evidence.

Key Issues/Current Debates

Landscape has provided a most fertile context where to explore several important aspects of the Roman world, from economy to imperialism and from demography to urbanization. As already pointed out, the crucial contribution has been represented by the recovery of a lively and densely populated countryside, thus prompting a significant reconsideration of the integrated relationship between town and country. Cities are no longer merely seen as passive "consumers" of the resources provided by their territories but rather as actively engaged in a complex symbiotic pattern of production, distribution, and consumption of goods and services. They obviously created demand for local rural production, but, being also part of a wider network of towns, roads, and ports, they in turn supplied their hinterland with imported goods and created a gateway through which further surplus could be sent/sold elsewhere. The notion that landscape and cities must be approached as distinct features of a unitary process is today firmly established (e.g., Patterson 2006).

Another important achievement of survey archaeology is having brought about the awareness that there existed several Roman landscapes (Barker and Lloyd 1991). As Roman rule gradually extended over many different regions with different environmental characteristics and long histories of previous human occupation, landscape patterns came to reflect a creative combination of imported ideas and local situations. Therefore, survey archaeology has contributed to effectively undermine easy generalizations about the nature of Roman imperialism, and the actual dynamics of these relationships are now understood to have varied as a result of the political and economic place each region occupied within a growing empire (Mattingly 2011: 123–99).

Placing such an emphasis on what is distinctive and different, however, is at risk of ingenerating a kind of relativistic attitude, an empirical myopia that impedes synthesis at a higher level. After all, what is distinctive emerges more clearly once similarities are appreciated. The need to compare, contrast, and combine data from different surveys is a long-debated issue among practitioners of Mediterranean archaeology. The problem rests on the fact that each project is designed in accordance with specific questions and that each research context will prompt the adoption of appropriate methodological choices to cope with its unique conditions (e.g., intensive/extensive,

total coverage/sampling). Such a variety of approaches does result in data whose uniqueness might not necessarily relate to original conditions and that would make comparisons difficult – if possible at all. What is remarkable is that a huge amount of data has been collected over the years and scholars increasingly feel the need to employ them in a way or another (Alcock and Cherry 2004; Attema and Schörner 2012).

From this point of view, Roman Italy has provided a much favored case study, having been extensively explored by a sheer amount of survey projects (Patterson 2006: 72–88). With all their possible differences, it is quite remarkable that most researches have classified Roman settlements according to broadly similar typologies: villas, farms, and villages. It is indeed possible to recognize two main working criteria: quantity and quality of finds. The former refers to the size of the surface spread, the number of finds, and therefore their density. The latter, on the other hand, is more concerned with what classes of material are recovered as indicative of function, status, and place of the site within the settlement hierarchy. Although the actual definitions might slightly change, villas are generally understood as large-size and high-status sites, farms as small-/mid-size and low-/mid-status sites, and villages as large-size and low-/mid-status sites.

Whereas farms and villages have been related with the Italian free peasantry, villas have been traditionally connected with large estates, owned by the elite and primarily worked with slaves. Traditional historical narratives pointing to the decline of the Italian free population, being in turn supplanted by slaves, would therefore require both a gradual disappearance of farms and a coeval growth of villas to have occurred. Remarkably, although this seems to have indeed occurred in some areas (central coastal Etruria, southeastern Italy), in the majority of cases, farms appear to have been much more resilient, usually growing in numbers at the same time as villas did (Launaro 2011: 149–164; Launaro 2017). Although this can reasonably be taken to suggest a growth of the free peasantry, it does not say anything in terms of actual numbers. Deriving absolute population figures from survey evidence is indeed a traditional ambition of Mediterranean landscape archaeology (Witcher 2011). In principle, it might sound like a rather straightforward exercise by which one multiplies the average number of occupiers by the number of sites. Besides the fact that there is no reliable way to guess such an average, the insurmountable obstacle is that surveyors simply cannot know how many sites they have actually missed. Although the inability to engage with both these crucial variables seems to seriously undermine any such effort, this has been repeatedly attempted following seminal work on the *suburbium* of Rome (Witcher 2005).

Recovery rates have always represented a critical issue. Surveyors have been frequently surprised by the rather limited amount of evidence for rural occupation dating to earlier phases of Roman colonization, and this was made more striking when contrasted with the number of actual colonists as reported by ancient authors. Although fieldwalking does still represent the best possible choice to detect smaller/poorer sites, it is ultimately dependent on archaeological visibility (Witcher 2011). By relying on fineware pottery or amphorae as the main diagnostic materials, surveyors often assume such goods/objects to have been evenly supplied in the first place. This has been shown to be not always the case, especially as one moves down the settlement hierarchy and away from the main distribution centers/networks (Millett 1991). This increasing awareness has brought about a general reconsideration of what surveyors should look for, and it has eventually become clear that commonware pottery could really make a difference as it was more readily accessed by all levels of urban and rural society (being mostly produced locally and at cheaper prices) (MacDonald 1995). Although commonware have always constituted the larger part of any plowsoil assemblage, their systematic and comprehensive study is yet to come. Some regional synthesis has indeed started to appear, but their general application is somewhat limited

by the very local character of the objects they endeavor to describe.

International Perspectives

As already mentioned (see section "Historical Background"), survey archaeology has its own origins in a long-established tradition of ancient topography to which scholars of many nationalities have since contributed to. Of course, one can identify some recurring patterns among practitioners and might be tempted to ascribe them to the existence of specific national traditions. For example, the impressive presence of still-standing archaeological structures across the Mediterranean countryside can in part explain the remarkable resilience of more traditional forms of ancient topography in those countries. It is fair to say, however, that such an attitude has evolved over the last 30 years and has since broadly merged with survey archaeology.

If a real opposition ever existed, it is perhaps that between the intensive survey championed by British archaeologists and the more extensive approaches favored by others (most notably, although not exclusively, American scholars) (Terrenato 2004). It is not specific to "Roman" surveys, but it represents the tension – latent in any archaeological fieldwork – between resolution and coverage. Ideally, both are needed. In practice, however, one comes at the expense of the other. If intensive fieldwalking is the only way to detect smaller/poorer sites, too limited a study area is at risk of being insufficient to represent the wider landscape. On the other hand, an extensive survey will certainly convey a much more global picture, but it is also likely to skew it towards the upper end of the settlement hierarchy, thus failing to provide a fair representation of it. The debate has never been settled and sampling strategies have only provided a partial solution to it. Relevant field practice across the Roman world has thus varied a great deal and is one of the reasons that have often prevented worthwhile comparisons from being achieved at the regional level.

Future Directions

Comparative regional syntheses do indeed represent the necessary step forward for survey archaeology in the Roman world. Although new data keep being recovered as new survey projects arise, the lack of integration and coordination between them – even within same regions – runs the risk of narrowing the perspective, thus leading to many unrelated local histories. In fact, if survey archaeology is to contribute to far-reaching debates about general historical processes whose scale transcended the individual landscape (see section "Key Issues/Current Debates"), scholars have to accept the challenge and envision ways in which these data can be profitably integrated. Although definitive results are still ahead of us, the last 20 years have witnessed an increasing number of attempts that – whatever their limitations or flaws – are demonstrating the way forward (Alcock and Cherry 2004; Launaro 2011: 80–83; Attema and Schörner 2012).

The role and significance ascribed to the plowsoil assemblage is also evolving. Although quantity and quality of finds are still eagerly employed to derive chronologies (i.e., in order to date sites), their distribution patterns across the landscape can be viewed from different angles accounting not only for supply but also for deeper social and cultural meanings mediated by choice or preference (Witcher 2006). In this view, the increasing knowledge of local Roman commonwares might not only provide more refined ways to date "marginal" sites but also could allow scholars to uncover a complex network of human relationships across the landscape(s) that would otherwise remain largely invisible.

Another growing tendency is to recognize the informative potential of "legacy data" (i.e., old data from past projects). While plowing brings to the surface otherwise hidden evidence, it keeps eroding and consuming such evidence until not only its visibility but its very existence is irremediably affected. The same goes for urbanization: it has never stopped and many more areas have been increasingly built over. This is further

complicated by the fact that the process of agricultural expansion of the post–Second World War era has now begun to reverse: lands are increasingly turned (back) to pasture or woodland, therefore dramatically affecting archaeological visibility. From this point of view, older surveys (from the 1950s, 1960s, to 1970s) do represent a mine of invaluable information: they documented surface evidence soon after it was plowed for the first time (i.e., higher integrity and better visibility) and explored extensive areas which are by now "concreted over" or, more generally, made unsuitable to survey. As new knowledge (e.g., more refined pottery classifications) and new techniques (e.g., GIS analysis) are made available, it becomes therefore possible to process the evidence again by answering questions and test theories which were not considered in the original research design (Witcher 2008).

Sustainability and Cultural Heritage

Lawrence S. Coben
Sustainable Preservation Initiative, New York, NY, USA

Introduction

The term "sustainability" has multiple meanings and uses in relation to cultural heritage. Most frequently, the term is employed in conjunction with or as part of such concepts as sustainable preservation, sustainable development, or sustainable tourism, though these concepts in practice overlap and are closely intertwined.

Definition

Sustainable Development

These concepts of sustainability derive from and grow out of the World Commission on Environment and Development's (the Brundtland Commission) 1986 report Our *Common Future*. That report defined sustainable development as "development which meets the needs of the present without compromising the ability of future generations to meet their own needs." (The term sustainable development first appeared in 1972 at the United Nations Conference on Human Environment in Stockholm.) This definition, while vague, called attention well to the problem of overexploitation and damage of natural resources in the pursuit of economic development and implicitly called for the practice of forms of economic development that better utilize and leave adequate natural resources for future generations. Sustainable development thus merges perpetual economic growth with the maintenance and enhancement of environmental values (Throsby 2002), thereby providing sufficient resources for both current and future economic development. The Brundtland Commission's discussion of

sustainability also included social and economic responsibility as important components of sustainable development, though in many discussions these components played a secondary role to the environmental one.

Key Issues/Current Debates/Future Directions

Sustainable Development in Cultural Heritage

In the latter part of the twentieth century and early part of the twenty-first century, scholars and governments began to consider and apply a modified concept of sustainable development to cultural heritage (see, e.g., Endresen 1999; MacDonald 2004). At times referred to as sustainable preservation, this discussion of sustainability has followed two distinct though related paths: first, the environmental and energy conservation benefits of the preservation and reuse of historic structures and, second, the potential economic and social benefits of the development of cultural heritage sites as touristic attractions or drivers of economic development.

Sustainable Development and Preservation-Historic Structures

Advocates of sustainable preservation argue that there are tangible ecological and environmental benefits from the reuse and redevelopment of existing historic structures. Such reuse may provide enormous energy savings and preserve resources by obviating the need to mine, harvest, produce, and transport new building materials. These savings may dwarf those of so-called "green" or LEED (Leadership in Energy and Environmental Design)-certified construction, particularly since the energy used to construct an average building is 15–30 times greater than its annual energy use (Rypkema and Cheong 2011a). Similarly, a 2011 report of the Preservation Green Lab of the National Trust for Historic Preservation noted, "Building reuse almost always yields fewer environmental impacts than new construction when comparing buildings of similar size and functionality." Current LEED standards give little credit for the environmental benefits of the reuse of historic or existing structures and none for the social and economic benefits.

Various metrics have been developed to measure the environmental benefits of historic preservation, including a building's embodied energy, lifecycle costing, avoided impacts, and reduced carbon footprint. All of these seek to measure energy usage, efficiency, and carbon footprint through the entire process of planning, constructing, and operating a building.

Sustainable Development and Preservation-Economic Development

Recognizing the increasing destruction of cultural heritage and sites from economic development and the potential to create jobs and revenues through tourism and preservation, governments, NGOs, and heritage practitioners have begun to consider the cultural heritage's potential as a driver of economic activity and poverty alleviation. The World Bank in numerous presentations has described its evolving approach toward cultural heritage as one that began with "do not harm," avoiding damaging cultural heritage while implementing other projects (1970–1980), to "specific intervention," investing in particular sites to develop tourism (1980–2000), to the current "integrated approach" that integratescultural heritage in local economic development with a focus on historic cities rehabilitation and sustainable tourism. The Inter-American Development Bank's approach has followed a similar arc.

These economic development projects all state that one of their goals is the sustainability or preservation of cultural heritage assets, allowing their use while preserving them for future generations. In addition to the environmental benefits described above, other suggested benefits include the creation of jobs; increased retail and handicraft sales and ancillary revenues, serving as a catalyst for local and regional development; the rejuvenation of declining towns and neighborhoods; gender inclusiveness; and a greater sense of cultural identity for local communities.

Metrics of project success have included jobs and household income, tourism visits and expenditures, and property values, as well as less directly economic social and environmental

impact studies (Rypkema and Cheong 2011b – see this article for a more detailed discussion of metrics and methodologies). However, measurement of the economic impact of sustainable development has been described as "nebulous" due to the difficulties of data collection (Rypkema and Cheong 2011b: 754), and data has been described as "hard to come by" (Silberman 2011: 48). While much anecdotal evidence of the economic benefits of sustainable development exists, to date there is almost no systematic analysis of the economic, social, or preservation benefits or return on investment of these expenditures.

In addition to disputing the economic benefits of sustainable development, critics have argued that sustainable development devalues the conservation and interpretation of cultural heritage. Other critiques of sustainable development have included the funding of projects that are not economically sustainable, damage and potential loss of access to sites as a result of touristic use and development, the commodification of heritage, displacement of local residents and other changes to local communities, and its lack of applicability to sites without touristic potential.

More recently, sustainability has also been used as a synonym for the stand-alone economic viability of development projects. Organizations such as the Sustainable Preservation Initiative define a sustainable project as one that is self-supporting after an initial grant or investment, in contrast to projects that will not survive without continued funding, normally by an NGO or governmental entity. Sustainable projects do not depend on the continued involvement of such an organization.

Sustainable Tourism

Almost every cultural heritage project includes a tourism component as one of its central features. In response to the potential damage caused by increased tourism, UNESCO, national governments, NGOs, and the travel industry have sought to create a form of tourism that respects and maintains cultural heritage. Sustainable tourism seeks to ensure that travelers conserve and protect both the natural environment and heritage assets, while promoting cross-cultural understanding. In some cases, an important component of this concept is that the tourism supports the community visited and patronizes entities that are locally owned or organized, particularly in poor regions. This issue of who should manage and benefit from tourism and economic development is frequently debated in discussions of sustainability. Many of the benefits and problems associated with this economic development are similar to those described above for sustainable economic development.

Sustainable Cultural Tourism Policies: Overview

Jessica Facciponti
University of Maryland, College Park, MD, USA

Introduction

For millennia, culture has been an integral part of travel and tourism. Travel to cultural and historical sites as well as to festivals, performances, and events has been recorded since antiquity (McKercher and Du Cros 2002). However, up until 20–30 years ago, tourism was largely seen as a benign industry with little negative environmental, social, economic, or cultural impact (Murphy and Price 2005). This lack of sustainable tourism planning and preparedness has resulted in cultural, economic, and ecological damage at many tourist destinations. As a way to address these problems, various nations and international entities have created policies calling for increased sustainable tourism planning and management. This entry will briefly discuss the relationship between culture and tourism, the development of international sustainable cultural tourism policy, and several of its prominent charters.

Definition and Historical Background

The relationship between culture and tourism first must be explained and historically traced in order to achieve a deeper understanding of sustainable cultural tourism policy. Cultural tourism can be defined as "visits by persons from outside the host community motivated wholly or in part by interest in historical, artistic, scientific or lifestyle/heritage offerings of a community, region, group or institution" (Silberberg 1995: 361). Even though a great percentage of travelers often have some element of cultural tourism in their travel itinerary, cultural tourism was originally associated as an activity of highly affluent and well-educated travelers (McKercher and Du Cros 2002: 151; Richards 2007). In the late 1970s, the tourism industry began to market travel for cultural reasons as a new and specialized form of tourism to the general public (McKercher and Du Cros 2002: 1). Then, by the 1990s, it began to be widely accepted and promoted as a mass tourist activity (McKercher and Du Cros 2002).

Tourism and culture have a dynamic and symbiotic relationship. An increase in tourism has a potential to benefit a site, a culture, its surrounding community, and the nation in which it is located. Its economic revenue can encourage the conservation and economic development of a cultural site, tradition, or community. For instance, intangible traditions on the verge of being forgotten in the community can become reinvigorated and preserved.

However, an increase in tourism can also cause substantial harm to a site and its host community. Since cultural and natural resources are finite, a surge of tourists and inadequate tourism planning may lead to cultural and natural resource damage and depletion, cultural and community exploitation, economic leakage, etc.

Thus, the regulation of cultural tourism is necessary to mitigate these negative impacts. Considering this, it is not surprising that the increased marketing of cultural tourism activities by the tourism industry coincided with the popular dawn of sustainable tourism and a spur in the creation of sustainable tourism policies (Butler 1998: 25).

Sustainable tourism falls under the multifarious sustainable development umbrella. It has been synthesized from the cultural and environmental concerns and the principles of sustainable economic development of the 1970s and 1980s. Sustainable tourism is not univocally defined; its definition and usage vary not only between stakeholders but also within and across disciplines. Among social scientists, sustainable tourism can be generally defined as the incorporation and monitoring of economic, social, and cultural goals in the planning and management of tourism at a site (Hall and Lew 1998; Murphy and Price 2005; Saarinen 2006). In addition, all sustainable tourism plans and policies, as Edgell states, should ideally strive to "integrate the economic, political, cultural and intellectual benefits of tourism cohesively with people, destinations, and countries in order to improve the global quality of life and provide a foundation for peace and prosperity" (1990: 1).

Key Issues

Sustainable cultural tourism policy has been influenced and evolved based on the international community's changing prevalent perceptions of and attitudes toward sustainable and cultural tourism. This section provides a chronological overview of key international sustainable and cultural tourism policies.

The first international cultural tourism policy, the Charter on Cultural Tourism, dates to 1976. It was preceded by substantial growth in the tourism industry and an increase in many governments and political entities' involvement in it due to their discovery of tourism's earning potential (Hall and Page 2006: 397). This increase in tourism's popularity and related discussions led to the United Nations XXI General Assembly designating 1967 as the "International Tourism Year," during which it passed a resolution called the "Importance of Tourism" stating that "tourism is a basic and most desirable human activity deserving the praise and encouragement of all peoples and all Governments" (United Nations 1967). However, cultural and sustainable tourism policy discussions did not become prevalent until the 1970s.

ICOMOS Charter on Cultural Tourism

In 1976, the International Council on Monuments and Sites (ICOMOS) held an International Seminar on Contemporary Tourism and Humanism. The Charter on Cultural Tourism is the result of this seminar. This charter was a revolutionary document in that it acknowledges tourism's irreversible "social, human, economic and cultural" effects, which had not been addressed before by an international body in writing (ICOMOS 1976). It also recognizes tourism as an important growing industry, but opposes "tourism's anarchical growth" and its negative consequences (ICOMOS 1976). To counteract tourism's negative effects on cultural and natural resources, it distinctly calls for conscientious tourism planning and policy regulation. It states, "with the future in mind. . .cultural and natural heritage which must take precedence over any other considerations however justified these may be from a social, political or economic point of view" (ICOMOS 1976).

In contrast, the charter also notes that tourism can have economic and cultural education benefits. It calls for the education of tourists, especially children, regarding the importance of the monuments and sites. Also, it recommends training for community members regarding how to evaluate and develop their relevant tourism site in order to safeguard it from tourism-related threats.

Unfortunately, this document focuses its cultural-based discussion primarily on tangible and monumental sites, which is referred to as "that privileged part of the human heritage" (ICOMOS 1976). Discussion regarding intangible cultural heritage tourism is notably absent, but this issue was developed in later policies over the next 20 years.

Manila Declaration on World Tourism

In October of 1980, Manila Declaration on World Tourism was developed at the World Tourism Conference. The declaration states that everyone should have the right to engage in travel and tourism (WTO 1980). It argues that states should encourage and support their populace's

engagement in domestic and international tourism in order to increase the following: social solidarity; national and heritage pride; cultural awareness; and international economic, sociocultural, and political cooperation. The declaration also advises states to provide tourism education and training for their populace (especially their youth). The Manila Declaration ultimately views world tourism as a means of promoting further steps toward world peace.

Furthermore, it asserts that world tourism is more than a "purely economic activity" and should not be the only reason a government chooses to endorse it (WTO 1980). Governments are encouraged to look beyond economic development to also consider and advance the social, human, and cultural dimensions of tourism (WTO 1980). Heritage tourism in this document is still perceived as and limited to physical and site tourism.

Brundtland Report and Agenda 21

By the mid-1980s, discussions concerning cultural tourism and sustainable development became prolific (Hall and Page 2006: 397). In 1987, the World Commission on Environment and Development (WCED) developed the Brundtland Report entitled "Our Common Future." The concepts of sustainability and sustainable development discussed in this document were later adapted for the tourism industry and influential in its sustainable tourism policies. A large concern of the WCED was intergenerational fairness and ethics (Butler 1998: 33). It states that current resource use and development should not compromise the future generation's ability to "meet their own [resource] needs" (World Commission on Environment and Development 1987).

This document and the later Agenda 21 developed at the 1992 United Nations Conference on Environment and Development (UNCED) helped spark sustainability discussions in the tourism field (Saarinen 2006: 1122). UNCED's Agenda 21 identified travel and tourism as a key economic sector with the possibility to make a positive contribution toward achieving sustainable development. It then spurred the formation of the Travel and Tourism Industry's Agenda 21 in 1996 (USAID 2005). Even though these policies primarily refer to the physical and natural environment, their perspectives on sustainable development also influenced future sustainable cultural tourism discussions and policies (USAID 2005).

Charter for Sustainable Tourism

In 1995, the Charter for Sustainable Tourism was created by the World Conference for Sustainable Tourism. It is influenced by the "principles set forth in the Rio Declaration on the Environment and Development and the recommendations arising from Agenda 21" (WCST 1995). The charter states that tourism must respect not only the economic and environmental structure of a destination but also the human dimensions and dignity of the local community in order to avoid negative impacts within the region.

The charter proclaims that the sustainable tourism effort should be a respectful and collaborative one with cooperation throughout all the tourism industry levels, including local, national, regional, and global. It calls for all tourism stakeholders and participants to work together toward the implementation of sustainable tourism activities. Moreover, it recommends that all governments and the United Nations try to develop sustainable tourism plans of action.

It advocates for tourism to "be integrated with the natural, cultural and human environment" (WCST 1995). Tourism projects and strategies should consider their effect on a local community's cultural heritage, aiming to protect not only their physical cultural sites but also their intangible elements such as local traditions and identity. In addition, it proposes that environmentally and culturally vulnerable areas as well as areas that have been degraded by high impact tourism receive special priority for aid and technical assistance.

Ultimately, the charter proposes that tourism planning and management should conserve and protect the natural and cultural heritage of a destination and its host community as well as enhance the local economic conditions while concurrently satisfying tourists' needs (WCST 1995).

The International Cultural Tourism Charter

The International Cultural Tourism Charter was established in October of 1999 by ICOMOS at its

Twelfth General Assembly meeting in Mexico. The Charter's ethos states that "a primary objective for managing heritage is to communicate its significance and need for its conservation to its host community" (ICOMOS 1999).

The charter notes the presence of a dynamic and reciprocal relationship between tourism and cultural heritage relating to economics, management, protection, and cooperation. It declares that there should be a tourism planning process dialogue between stakeholders, which focuses on the equitable treatment of present-day host community, indigenous custodians or the owners of historic property, and the descendant communities and cultures from which that heritage evolved.

Additionally, it proposes that cultural tourism activities should be enjoyable and educational for visitors while also respecting and enhancing the heritage and economic conditions of the host community.

The charter proclaims a duty of respect for heritage objects and values and promotes their management in a sustainable manner for current and future generations. It also discusses the importance of protecting a site and community's "authentic" tangible and intangible cultural heritage (ICOMOS 1999). Moreover, it encourages the use of "detailed, measurable goals" in the cultural tourism planning and policy-making process, especially with regard to the promotion, presentation, interpretation, and protection of heritage areas and cultural activities (ICOMOS 1999).

This charter implicitly suggests that when cultural heritage tourism is adequately managed and planned, it will result in economic and community benefits. As a result, it tries to anticipate and mitigate any possible problems. However, in this short document, it is impossible to analyze and cover all the possible factors that can lead to tourism complications and negative outcomes.

Global Code of Ethics for Tourism

In 1999, the General Assembly of the United Nations World Tourism Organization (UNWTO) adopted the Global Code of Ethics for Tourism. This code of ethics advocates "maximiz[ing] the positive economic, social and cultural effects of tourism . . . while minimizing its negative social and environmental impacts" (UNWTO 1999). It states that all tourism participants should be responsible to uphold this code of ethics and to practice ethical tourism. Thus, tourists should try to protect not only themselves but also the environment, culture, and people of their destination's host communities. In addition, governments and other authorities need to be attentive to and spread awareness about the social, cultural, and environmental vulnerabilities that affect host communities as well as tourists. Local communities should be able to express their culture, livelihoods, and religion, but they should be careful to avoid infringing upon the tourists' beliefs and security.

The UNWTO believes "tourism is a user of cultural heritage of mankind and a contributor to its enhancement" (UNWTO 1999). This code promotes a global human heritage of which everyone is a part and shares, but the local community has specific rights and obligations to the maintenance, profits, and safeguarding of its heritage resources (UNWTO 1999). It promotes the use of sustainable policies and plans that will protect and support cultural heritage resources, traditions, performances, and crafts in order to allow them to thrive and flourish and be accessible for future generations to experience.

Future Directions

Since 1999, there have not been any new prominent international sustainable cultural tourism charters. However, there is a need for change since the implementation of the aforementioned sustainable development and cultural tourism policies has proven to be difficult. They have been sporadically and erratically applied, if at all. This is partly due to their vague and fluctuating policy criteria, assessment standards, and definitions (Font 2005; Murphy and Price 2005).

There is a need for a more consistent framework for which to evaluate tourism programs in order to ensure operation is in accordance to international standards. However, the framework would have to be flexible enough to fit the unique needs of each tourism program. Also, the concepts

that would be involved in that assessment are quite complex, and one has to be cautious in employing them (Murphy and Price 2005: 178). For instance, it may be found difficult to set a minimum level for sustainability, and if one is set, it can discourage others from going above and beyond that level especially if financial incentives are involved.

Furthermore, there are often a plethora of tourism stakeholders at various power levels who can negatively affect the regulation of sustainable cultural tourism. The regulation can be viewed as a local, regional, national, and global issue simultaneously, which can result in a higher likelihood of overlapping regulatory agencies and policies. Ultimately, the best way to ensure the utilization of international sustainable cultural tourism policy is through the collaboration and corroboration of all stakeholders.

Worldwide Historical Perspectives

Relations between Egypt and sub-Saharan Africa had already been established since the Pharaonic period. Sailors set sail for the land of "Punt" (Meeks 2002; Tuchscherer 2004), to the south of the Red Sea, in order to bring back incense, ivory,

and slaves. At the beginning of the first millennium CE, the discovery of monsoon winds and how they could be used started a veritable nautical revolution which meant that very long journeys to India and Ceylon were possible. The Egyptian port of Berenice maintained trading relations with the Indian port of Barygaza and the African port of Rhapta (Keswani 1980: 41). Throughout Antiquity, the coastline from Somalia to Zanzibar had been known as Azania. For knowledge of the African coastline during the Greco-Roman period, the two major texts that are used are the "Periplus of the Erythraean Sea," an anonymous document drawn up in Alexandria in 60 of "our era," and the book written in 150 AD by Claudius Ptolemy, a Greek from Alexandria, entitled "Ptolemy's Geography" (Freeman-Grenville 1962: 1–3; Gray 1963: 9–30). Ptolemy mentions the lands of Zengis to the south of the Aromatic Cape (Cape Guardafui). Zengis/Zeng is apparently a term derived from the Greek for "arid" and thus denotes the African lands and black people. In 547–549 AD, another Egyptian (a native Greek merchant from Alexandria), Cosmas Indicopleustes, talks about Zingion, to the south of the land of the Barbarians (Devic 1883: 18). These authors mention numerous trading entrepôts located along the East Coast of Africa. Further on than the Barbaric land is Port Opone which heralds the beginning of the Aromatic Coast (the coast of the Somalis), and then the land curves southward and the ships reach the Azanian coastline (Desanges 1999: 348). The first port on this coast is called Sarapion followed by Nikon (Barawa or Bur Gao) (Freeman-Grenville 1962: 21–22) and the mouths of several rivers. The ships reach the Pyraliean islands (the Lamu Archipelago) (Mathew 1963), and after 2 days travelling along the Ausanitic Coast ("Azania"), the travellers catch sight of the flat and forested island of Menouthias (Zanzibar) (Clark and Horton 1985: 34). Another 2 days travelling are needed to reach the final marketplace on the coast, known as Rhapta.

The Sassanians became great trading intermediaries, following the weakening of the Roman Empire and the collapse of the Parthian Empire. They controlled the majority of the maritime routes of the Persian Gulf from the third century of "our era." The Sassanians and the Aksumites became the predominant navigators of the Red Sea and the Persian Gulf, and this was the case up until the sixth century (Desanges 1999: 351; Keswani 1980: 41). The Sassanian King Ardashir I established his capital at Ctesiphon and subjugated the Kingdoms of Kushan, Turan, Makran, and Bahrain (Fiorani and Besenval 1990: 133–134 and 136–140; Piacentini and Besenval 1990). At that time, the large Sassanian ports of Sohar and Siraf channeled all the wealth that was transiting between Africa and India. Moreover, the Sassanian King Vahram V (r. 421–438) even married an Indian princess from whom he received a dowry in the form of the city of Daybul; this Indus Delta port was the meeting point between Aden and Sri Lanka (Carswell et al. 2013: 40–52). The Christian Aksumite Kingdom was at its height between the fourth and sixth centuries and the large Aksumite port of Adulis acted as a relay from Alexandria on the Red Sea before the advent of Aden. Cosmas Indicopleustes recounted his journey through Adulis en route to Ceylon in 525 AD (Freeman-Grenville 1962: 5). Once the ships arrived in the Gulf of Aden, they did not travel directly toward India or Africa, but were replaced by either Aksumite or Yemenite ships (Desanges 1999: 323). It appears that Roman trade was relayed indirectly by Yemenite, Indian, and African intermediaries.

Although trade between East Africa and the Persian Gulf was disrupted in the seventh century, it saw a resurgence in the eighth century. However, the relationships with the merchants were different as the Muslims started to settle in Africa and to stimulate African urbanization. Among the earliest medieval testimonies, one of the most extraordinary is that of Du Huan, an officer in the Chinese Army. Captured during a battle at Tashkent in 751, Du Huan was enslaved and led into the region of Baghdad. In 761, he accompanied some Persian dignitaries along the coasts of Sudan and Eritrea. The following year, he managed to return to Canton where he wrote an account of his travels, the "Jingxingji" (Smidt 2001: 17–28). From this adventure we learn that

crews from the area around Baghdad visited the African coasts from the eighth century.

In the ninth century, Persian ships departed principally from Sohar and from Siraf, the port of Shiraz. The most famous tale of a Persian navigator is still "The Adventures of Sinbad the Sailor." The adventures of this sailor-cum-merchant apparently took place between 806 and 807 (Casanova 1922: 172). During his second voyage, Sinbad reached the region of al-Qumr which includes the Comoros Archipelago and the north of Madagascar. Many myths and legendary characters still remain like these dog-headed cannibals (Devic 1883: 111–113), which were possibly the Lemurians of Anjouan or of Mayotte in the Comoros Archipelago. Of course, there is the "Roc," the legendary giant bird of prey which was undoubtedly the Aepyornis of Madagascar. In Hormuz Port, Sinbad mentions that African ivory tusks were sold. During his fifth voyage, Sinbad visits Somalia and the eastern coast up to Anjouan and the island of Mouyâ (Mayotte?) where both cinnamon and pepper grow (Khawam 1985: 67, 170–171 and 211). Aloeswood apparently comes from the island of Chadjî located 5 days' journey time from Comoros and was, undoubtedly, the Maldives. Sinbad travelled along the African coasts, and then, via Comoros, he directly rejoined the Maldives up to the Indian coasts. This important information is corroborated by other texts written by contemporary Arab geographers (Planhol 2000: 93) such as Oubayd Allah Ibn Khorradâdhbih in 846 and Dja'far al-Marwazî in 887. Thus, from the ninth century, there were two great maritime routes between Asia and Africa (Sauvaget 1954), one which ran along the Arabian Peninsula and conveyed the ships which depended on the Omani and Yemenite coasts and the other which headed straight across the ocean (Fig. 1). These sources indicate that as early as the ninth century, there were major shipping routes between Asia and Africa.

Written Arabic sources became more frequent during the tenth century. From al-Masudi's testimony in 916, we learn that many ships belonged to the Omani and Sirafi sailors Masûdi. Xth c. (Meynard ed. 1970). From the tenth century, the Arabs noticed that the Zanj were speaking in a different dialect than that of the blacks who lived inland, something which could mean that the Swahili language traced its origins to this precise moment (Freeman-Grenville 1962: 16). According to the Kilwa Chronicles (Freeman-Grenville 1962: 34–49), the first Shirazi princes arrived on the island in the tenth century. Not all the Africans living on the coastline were Muslims, and there were still many idolatrous pagans left. It was only the city of Qanbalû that had an Islamized population with a king known as the Mfalme. The city of Qanbalû is mentioned in 945 by Ja'far b. Râchid, also known as Ibn Lâkîs, the famous captain. Ibn Lâkîs recounted the attack on Qanbalû by about a thousand pirate ships from the land of Waq-Waq (Planhol 2000: 113–114 and Bacqué-Grammont 2007) which it seems came from Madagascar and apparently travelled up the African coast for a year and pillaged many cities along the Zanj Coast, notably Sofala. The city of Qanbalû was apparently built in the middle of an estuary, on a peninsula/island, and surrounded by a city wall (Freeman-Grenville 1962: 9–17; 39–40 Shepherd 1982: 133; Horton and Middleton 2000: 66).

Another sailor's account from the Persian Gulf was written in the middle of the tenth century (Buzurg b. Shahriyâr 953 [1954]: 189–309). Buzurg ibn Shahriyâr was originally from Hormuz Port and he wrote 'The Book of the Wonders of India' (Planhol 2000: 101; Ibn Khurradadhbeh 885 and Ibn Ḥawqal 988; Freeman-Grenville 1962: 9–13). The text provides very important information on the products traded between Africa and Persia. In the text he mentions not only the gold mines of the Zanj country, but also the African slave trade in the tenth century. Having left Oman en route to Qanbalû in 922, Buzurg ibn Shahriyâr's ship was driven off course toward Sofala (a city in the Zanj land) by the ferocity of the winds. The sailors were warmly welcomed there and they began bartering. Taking advantage of the hospitality and naivety of their hosts, Buzurg decided to abduct the king of the Zanj people and seven of his followers when their ship was departing. The king was placed down in the hold with 200 other captives and was then sold as a slave at al-Basrah where he converted to

Swahili Archaeology, Fig. 1 Map of the Indian Ocean marking the locations of the principal medieval ports

Islam; then he was sent to Baghdad. Following a pilgrimage to Mecca, he escaped and headed for Egypt and, after a long journey, returned to his country. By coincidence, years later, the winds carried Buzurg and his fellow travellers back into the same African area, where, faced with their cowardice and the crime committed, they took fright when they recognized the king whom

they had previously captured. However, the king, full of grace, forgave those who had sold him as a slave: was it not predestined anyway that he should become Muslim? The *Book of Wonders* also indicates that the king converted his people. This very short story of conversion is extremely interesting as it is one of the earliest accounts of Islamization in East Africa and also a testimony of the slave trade for this period.

The period from the eleventh to the twelfth century was a period of transition, with the prestige of Baghdad on the decline in favor of Fatimid Cairo, the great new Islamic metropolis. Also, the Sulayhid Dynasty of the Yemen was to maintain close ties with Fatimid Egypt from 1084 to 1138 (al-Bakri 1094 (1965) and Moncelon 1995: 29–30). The merchants of the Persian Gulf remained very active, but they preferred other ports, often on islands such as Qish, Hormuz, and Bahrain. The earthquake that destroyed Siraf, the port of Shiraz, in 977 and the fall of the Bûyides in the eleventh century led to a massive exodus of Persians who emigrated toward the island of Qish and the island of Hormuz in the Persian Gulf, but also to Jeddah in the Red Sea. It appears that this exodus of the Shirazis was a phenomenon that affected all the Indian Ocean as the majority of old Swahili cities were apparently founded by the Shirazis. Axelle Rougeulle also stated that the Yemenite port of Sharma, on the banks of the Hadramawt (Rougeulle 2015), was founded and occupied from 980 to 1150. Many African urban centers were created between the eleventh and twelfth centuries, and the stone architecture was developing with coral sea stones (*Porites*) cut in small regular ashlars first for the mosques and the storehouses (Pradines 2009: 67–70). The Swahili city-states were being set up at this time. Al-Idrîsî, working at the Court of the King of Sicily, is our main contributor when it comes to information about the East Coast (Idrisi 1154 (1968)). His geographic compilation *Nuzhat al-Mushtaq fi Ikhtiraq al-Afaq*, dating from 1154, describes Malindi and Mombasa as great African cities and also speaks about the island of Angazidja (Anjouan) and of Sufala, the Golden Land (Freeman-Grenville 1962: 19; Guillain 1856: 205–206 and Ferrand 1891). Most of his descriptions are probably knowledge collected earlier by the Fatimids who knew very well the coast of East Africa that they described in *The Book of Curiosities: An Eleventh-Century Egyptian Guide to the Universe* (Rapoport and Savage-Smith 2014: 437–446).

The thirteenth century was a period of political changes in the Muslim world. The stability was established with the Ayyubids and then the Mamluks in Egypt and the Rasûlids in the Yemen (Freeman-Grenville 1962: 45). The Shirazi Dynasty of Kilwa was replaced by the Mahdali Dynasty, a Hadhrami tribe from the south-west of the Yemen. This new power is linked to the Seljuqs of the Persian Gulf as well as to the Indians of the Indus Delta and the Deccan. The Arabian Peninsula's position strengthened therefore from the thirteenth century with the ports of Aden and Shihr. The Swahili coastline was divided into several independent sultanates (Barros 1552 II, 21), including Kilwa, Mombasa¸ Malindi, Pate, Merka, and Mogadishu, which were described briefly by Yâkût in 1212–1229 (Yâkût 1224 (1964)). Other more confused sources spoke about the African coast; for example, in 1295, Marco Polo provided a Chinese description of Mogadishu and Zanzibar (Freeman-Grenville 1962: 42). However, we had to wait for Ibn Battûta to have, in Battûta 1331, and Abulfida in 1342 (1848) a detailed and precise description of the cities on the Zanj Coast (Ibn Battuta 1854 edition: 179–196 and Freeman-Grenville 1962: 27). Ibn Battûta provided us with a detailed description of the East Coast (Reinaud 1848: 206–208; Guillain 1856: 299–300). The city of Zeila was the capital of the Berbers, the Shafi'ite blacks. Then came Mogadishu and the city was ruled by Sultan Sheikh Abu Bakr ibn Sheikh Omar, and his qadi was an Egyptian eunuch. The religious rituals were identical to those of the Yemen. Ibn Battûta noted that Mombasa was a great city. Apparently, Kilwa was one of the most beautiful cities in the world with its stone houses, mosques, and palaces (Freeman-Grenville 1962: 25–33). The inhabitants of Kilwa, like all the coastal dwellers, were Sunni Shafi'ites. From the fourteenth to the fifteenth century, Kilwa held the monopoly on gold trading, and Ibn Battûta

specified that the Sofala gold came from Yufi, in the land of the Limis, located within 1 month's walking distance from the coast. Sofala, which was a vassal of Kilwa, maintained trading relations with the Shona kingdom of Great Zimbabwe, where the gold mines were situated. The rise of Great Zimbabwe was intimately linked to the trading of gold with Muslim merchants and not due to the cattle theories.

The coast's political situation was still evolving at the beginning of the fifteenth century, and certain city-states were beginning to have very important territories; attempts at state control of the principalities of Pate, Mombasa, and Kilwa were being seen here. Toward the end of the fifteenth century, technical literature relating to navigation appeared, and these works described the African coasts in detail. The most famous nautical route maps were those of Ibn Madjîd (1475–1478 and 1495–1496) and those of Sulayman al-Mâhrî (1511–1512). Apart from a geographic description of the places, these texts provided much information on the main trading players in the Indian Ocean. In the Sofâliyya, Ahmed Ibn Madjîd noted that numerous captains came from the Zanj (Ducatez 2003: 139; de Planhol 2000: 115–117). This observation is noteworthy, and it teaches us that the African sailors crisscrossed the Indian Ocean alongside the masters of navigation who, according to Sulayman al-Mâhrî, were the Arabs from Hormuz, the Gujarati, and the Cholas from India.

In 1498, Vasco de Gama opened the route to India, and, at this time, his scribe, Alvaro Velho, recorded a lot of information on the state of the Swahili cities prior to the Portuguese domination. In 1505–1506, the anonymous journal of Francisco d'Almeida's voyage described the rebel cities of Kilwa and Mombasa. The Portuguese sources of the sixteenth and seventeenth centuries, such as João de Barros, Castanheda, Correa, Duarte Barbosa, João dos Santos, and Francisco de Monclaro, were plentiful and contained extensive detail of the commercial and political alliances of the coastal people (Strandes 1899). The European objective was to control eastern trade markets. They possessed two important technological advantages that ensured their domination of the Indian Ocean: the use of firearms and large, fast boats, caravels. The Portuguese built some 50 forts around the Indian Ocean, from Mozambique to Malacca, occupying the coasts of Kenya and Tanzania during the sixteenth and seventeenth century (Pradines et al. 2016: 50–75). Despite founding some trading posts, they quickly abandoned any attempt at political hegemony and were content keeping control of the sea routes.

At the end of the seventeenth century, the area saw significant conflict involving Portuguese and Omani forces. After the fall of Mombasa in 1697, the Imam of Oman sent governors and garrisons to large cities such as Pate, Lamu, Mombasa, Zanzibar, and Kilwa. In 1832, the Omani capital was transferred to East Africa and the Sultanate of Zanzibar was founded (Anene 1966: 440–457). The Sultanate of Zanzibar required a lot of slaves to maintain its clove plantations, the main export product. Large caravans were organized by the Omanis who destroyed the indigenous populations' economy and introduced firearms in exchange for slaves and ivory. These slave caravans were funded by wealthy Indian merchants, the *banian*s (Alpers 1976: 22–44). But the commercial force of the Sultanate of Zanzibar was also its weakness, its plundering economy being based solely on slavery and the export of tropical products such as ivory and cloves and the limited number of these products increasing the precariousness of the economic system (Burton 1872; Miège 1982: 293–318). The direct slave trade brought about important social changes, with Swahilis using landward populations rather than venturing beyond the coastline. For the first time in the history of East Africa, Islam took root in the interior lands of Kenya and Tanzania, right up to the Great Lakes region. In 1876, the movement of slaves toward the coast was strictly prohibited. The prohibition of the slave trade and the development of steam navigation eventually destroyed the supremacy of the Omani fleet. The opening of the Suez Canal imposed one last blow on the Sultanate causing it to lose its primary markets. The last sultan, Sa'îd Barghash, died in 1888 and Zanzibar became a British protectorate on 1 July 1890.

The Swahili: A Muslim Culture from East Africa

The Swahili coast is a stretch of land that extends from Mogadishu in Somalia to the Bay of Sofala in present-day Mozambique. The Muslim geographers divided the coast into four regions: firstly, the navigators reached the *land of the Barbarians*, the Bilâd al-Barbar, and then came the *land of the blacks*, known as the Bilâd al-Zanj, located between the Shebelle River and the island of Zanzibar; then they arrived at the land of the Sofala, the Bilâd al-Sufâla, also called *Sofala the Golden* or Sufâla al-Dhahab, the area between the mouths of the Zambezi and Limpopo rivers, and finally some sailors travelled right up to the land of the "Waq-Waq," a land that comprises Comoros and the large island of Madagascar.

Etymologically speaking, "wa-swahili" means the people of the "Sahel," the Arabic term for the "shore." This appellation dates back to the colonial period and the nineteenth century, with the Muslim geographers (al-Masûdi, Idrîsî, Yâkût, Ibn Battûta to Ibn Khaldûn) preferring the appellation "Zanj" which not only referred to the inhabitants of the East African coasts but also to black people in general (Freeman-Grenville 1962: 29). This term comes from antiquity and from the Greeks who used the name "Azania" to denote the African coasts. The Portuguese also noticed a difference between continental Africans and the people of the coast, who in light of their religion and customs they equated with "Moors" or "Kaffirs." The Swahilis have defined between themselves according to their region, island, or town of origin. For example, the people from Mombasa refer to themselves as wa-Mvita. Despite some common ground, Swahili identity remains multiple, incorporating populations of diverse background, Nilotic Cushitic, Bantu, and Austronesian.

The Swahili civilization stands at the periphery of the Muslim and African worlds, resulting in the development of a unique coastal culture based on trade. In fact, its marginal position is linked to our vision of the Indian Ocean, which separates Africa, Arabia, and Asia. But the ocean also provides a connection between these very different cultures: the Swahilis are thus dynamic players, equal to Arab, Persian, and Indian traders. As well as religion and language, these coastal populations share the same social organization and architecture. More than 450 Swahili archaeological sites have been registered spread over 3000 km of the coastline (Pradines 2004: 18–20). The lifestyles on the East Coast, Comoros and Madagascar, were homogenous due to the dissemination of new ideas and techniques by maritime travellers. Swahili culture reflects neither a specific ethnic group nor a particular nationality.

Historiography of the Research

The precursors of Islamic archaeology in East Africa are the explorers of the late nineteenth century who did what we call today pluri- or multidisciplinary research. They recorded information's and data about people and monuments, describing indistinctively nature and culture in an encyclopedic manner. In 1856, Charles Guillain wrote the first historical report on the east coast of Africa, while R. Brenner visited sites in the archipelago of Lamu, Mambrui, and Malindi in 1868. Richard Burton mentioned ruins in Zanzibar and Tanganyika in 1872. But it was Georges Révoil who carried out the first research, digging several trenches in Mogadishu in 1882. Révoil's contribution is very important for archaeology, as he published many buildings that today have disappeared or fallen into ruin (Révoil 1885/1888). Photographs were also taken by Sir John Kirk who visited Gedi and Lamu in 1897. Captain J. Stigand published photographs of Lamu, Takwa, and Pate in Stigand 1913. F.B. Pearce initiated the first research into Zanzibar and Pemba in 1920; he was followed by W.H. Ingrams in Ingrams 1931 and L. Buchanan 1 year later. The ruins of Kilwa were declared heritage-listed monuments and were restored by a German team in 1935. The pre-WWII period was thus characterized by a rising awareness of the historical value of Swahili archaeological sites.

The first scientific archaeological excavation on a medieval Swahili site can be traced to 1948. A disciple of Mortimer Wheeler, James Kirkman, was sent to Kenya to excavate and protect the site of Gedi. Mythic stories had been circulating about this lost city, which was believed to be the work of Phoenicians or Egyptians lost on the African coast. The excavations lasted 10 years, until 1958, and the results were published in 1954 and 1963 (Kirkman 1954, 1963, 1964). Kirkman also investigated two other major sites, the city of Ungwana in north Kenya and the Fort Jesus in Mombasa (Kirkman 1966, 1974). The museum of Fort Jesus opened to the public in 1960 and was managed by Kirkman until 1972. As early as 1948, Kirkman founded the Coastal Archaeology Unit of the National Museums of Kenya. This department was originally based in Lamu but was later transferred to Fort Jesus. Its current offices are located in the former courthouse of East Africa, in Mombasa. The role of this department is to record, monitor, and protect more than 120 historical and archaeological sites along the coast of Kenya, with its researchers conducting rescue and research operations on endangered sites. Kirkman made numerous excavations and topographical surveys in Takwa, Kilepwa, Kioni, Mnarani of Kilifi, Jumba la Mtwana, Kinuni, and Ras Mkumbuu on Pemba Island. The 1950s was also marked by archaeological surveys conducted by Mortimer Wheeler and Gervase Mathew in Kilwa and Songo Mnara. In 1964, James Kirkman published the first monograph on Swahili archaeological sites: *Men and Monuments on the East African Coast*. Significantly, he refused to attribute the invention and use of coral limestone architecture to Africans, preferring to see it as the result of Arab or Persian colonies. According to Kirkman, only foreigners could be the cause of urbanization, where towns were established as Arab trading posts, not as African cities.

A second important figure in Swahili archaeology, Neville Chittick, was appointed director of the *British Institute in Eastern Africa* in 1962. This Institute, founded in 1960, had as its principal goal, the promotion of archaeological research in East Africa. Chittick was particularly interested in the medieval cities on the Kenyan and Tanzanian coasts. During the 1960s and 1970s, he undertook two major excavations, one in Kilwa in south Tanzania and the other in Manda in north Kenya (Chittick 1974, 1984). Chittick also initiated excavations in Songo Mnara, in Kisimani on the island of Mafia, and in Pate in the Lamu Archipelago, explorations in Somalia, and surveys in Mogadishu. Problems with Chittick's work were his lack of interest in the ancient pre-Islamic occupations of Kilwa and his classification of African pottery called "cooking pots." Nevertheless Chittick published more African ceramics than most of the scholars who nowadays criticize him. Unfortunately the job of an archaeologist is to collect data first and then to write about them. Ceramic drawings are not an option but a part of the job.

In 1966, the work of Peter Garlake, *The Early Islamic Architecture of the East African Coast*, was published and is considered a milestone in the study of Swahili architecture (Garlake 1966). Garlake did a systematic inventory of all the ruins on the Tanzanian, Kenyan, and Somali coasts. He analyzed the evolution of local Swahili architecture and integrated it into the wider Islamic world. Unfortunately he stayed focused mainly on mosques and palaces (except for the town of Songo Mnara that he described in detail). In the 1970s, Thomas Wilson identified 450 to 500 stone establishments extending from Warsheikh to the north of Mogadishu and to the Bay of Sofala in Mozambique. Wilson's work arguably initiated reflection on the articulation of Swahili territories and Swahili urbanism (Wilson 1978, 1980, 1982).

In a 1962 publication, the famous historian Freeman-Grenville conceded that Swahili towns could be of African origin. But it's in 1974 that James de Vere Allen affirmed the African origin of the Swahili towns in his talk, "Town and Country in Swahili Culture," during the Leo Frobenius symposium in Cologne. In a 1981 article, he argued that Swahili urbanization and culture were exclusively Africans (Allen 1981: 306–334). Unfortunately, this research on "African roots" resulted in aberrations during the 1980s and later (Kusimba 1999; Chami 2006). The posthumous work of James de Vere Allen mentions the presence of an African state in the ninth

century, the Great Shungwaya. Allen argued that this state, located in what is now southern Somalia, consisted of Cushitic-speaking peoples who later dispersed and founded the Swahili towns. This Afrocentrist vision was pure fantasy and not based on any archaeological or historical evidence. The same views were presented in the *General History of Africa* published by UNESCO; Henry Mutoro declared: "The material forms assumed by Swahili culture present no analogy with Arab or Persian civilizations. There is no exact correlation between Swahili stone constructions and Middle Eastern, Arabic and Persian architecture, which leads one to suppose that it drew its inspiration from the latter" (Masao and Mutoro 1990: 645). After the colonialist vision of Arab-Persian trading posts, the postcolonial Europeans and Africans both became engaged in the elaboration of a new ideological model, the Africanization of Swahili cities, a theory supported by the myth of Shungwaya (Mutoro 1987; Chami 1998: 199–218).

In the meantime regional studies were conducted. In the 1970s, Pierre Vérin initiated archaeological research in the north of Madagascar (Vérin 1975). His team engaged too with the study of the Comoros, with Claude Allibert and Daniel Liskowsky who continued the research started by Henry Wright in the 1980s (Wright 1984). In 1980, Mark Horton undertook excavations in Shanga, in the Lamu Archipelago (Horton 1996). His excavations, held between 1980 and 1988, focused on the Islamization of this coastal area. Horton was the first archaeologist to focus on the early phases of coastal sites, in line with Africanist views of his time, but bearing in mind the historical continuity linking the African indigenous populations to the new Muslim settlers at the end of the first millennium CE.

In 1986, Paul Sinclair launched a project looking at the urbanization of East Africa and in particular of Mozambique. This project united institutions in Botswana, Comoros, Kenya, Madagascar, Mozambique, Namibia, Somalia, Zimbabwe, Tanzania, and Zanzibar, strengthening archaeological research in these developing countries and collecting and publishing the results of excavations carried out by local researchers (Sinclair et al. 1993). Due to this ambitious project, major African archaeologists emerged in the 1990s, including Félix Chami in Tanzania, Ricardo Duarte in Mozambique, Ahmed Jama in Somalia, Chantal Radimilahy, and more recently Abdurahman Juma *in Zanzibar* (Duarte 1993; Chami 1994; Jama 1996; Radimilahy 1998; Juma 2004). Finally in the late 1990s and the early twenty-first century, Adria LaViolette started to work on Swahili domestic architecture of the mud and thatch houses (La Violette and Fleisher 2009: 433–455). She developed an archaeology of the poors, "the invisible majority." Pradines started new excavations in Gedi in Kenya and Songo Mnara in Tanzania with a focus on urbanization, Islamization, and international trade in the Indian Ocean (Pradines and Blanchard 2005: 25–80). Jeff Fleischer and Stephanie Wynne-Jones continued LaViolette's approach by looking at spatial analysis and developing a social archaeology based on theoretical models mainly in the Kilwa region. Very recently excellent studies were conducted in understudied regions and themes by young scholars such as Edward Pollard on the foreshore and intertidal zones of Swahili landscapes, Martial Pauly in Mayotte (French Comoros), and Jorge de Torres in Somalia (Pollard 2008; Pauly 2014; Torres 2017). Except Chittick, Horton, and Pradines, most of the archaeologists who worked on the Swahili coast were Africanists by training, and this influenced a lot the research themes developed since the last 30 years.

Key Issues/Current Debates: Architecture and Muslim Identity in Sub-Saharan Africa

The origins of Islam in East Africa and the study of the first Swahili mosques were investigated by Horton's excavations in Shanga (Lamu, Kenya) and Pradines in Gedi (Kenya), in Songo Mnara, and Sanjé ya Kati (Kilwa, Tanzania) (Horton 1996; Pradines 2009, 2010) (Figs. 2 and 3). According to oral traditions on the Swahili coast, the first stone mosques were associated with the Shirazis. The so-called Shirazi mosques date back

Swahili Archaeology, Fig. 2 Excavations of the Great Mosque of Gedi (Malindi, Kenya)

Swahili Archaeology, Fig. 3 Excavations in front of the *mihrab* of the mosque of Songo Mnara (Kilwa islands, Tanzania)

from the eleventh to the twelfth century; these mosques seem to have had consistent proportions; in Gedi, the first mosque was *c*. 10 by 7 m. In Tanzania, the Great Mosque of Kilwa was erected between 1131 and 1170, and its initial rectangular plan does not differ from the model previously described, measuring 11.8 by 7.8 m. Also in the Bay of Kilwa, the island of Sanjé ya Kati houses a large mosque founded in the second half of the eleventh century, measuring 10.21 by 9.46 m. In Shanga, the mosque, constructed in Shanga between 1015 and 1035, forms a rectangle measuring 11.22 by 7.21 m. The Islamization of the African coasts was connected with Shi'a communities from the Persian Gulf (Pradines 2009). The oldest-known Swahili *mihrab* is indicative of these transoceanic influences. The *mihrab* of Kizimkazi on the island of Zanzibar is decorated with a passage from the Qur'an and bears the date 1107 (Flury 1922). The niche is decorated with

floral Kufic inscriptions along the capitals and within the apse. The islands of Bahrain and Zanzibar share this particular type of *mihrab* (Kervran 1990: 31, 48). In Bahrain, the Suq al-Khamis Mosque has a floral Kufic inscription with a Shi'a inscription mentioning the Twelver imams.

In the thirteenth to the fourteenth century, stone architecture became widespread. And eventually mosques reached large dimensions, such as that in Gedi, 26 m long at the end of the fourteenth century. From this period, the walls of the buildings were erected using a formwork of irregular stones embedded in lime mortar. Swahili mosques have a rectangular prayer hall flanked by narrow lateral wings usually comprising one-third of the width of the central hall. These mosques do not have a minaret and are bordered by a small courtyard where ablutions are practiced (generally to the South or East). Some mosques comprise a central row of pillars, facing the mihrab. The niche of the mihrab is in the form of a square, not integrated into the wall but jutting outside the mosque. The plans of Swahili mosques have a number of similarities with their counterparts in Southern Arabia, notably on the shores of the Hadramawt and Oman. In the fifteenth century, the mihrab of the Great Mosque of Gedi was decorated with 13 blue and white porcelain vessels inserted into the tympanum and the lower side of the apse. This use of ceramics as a decorative element of the qibla or the Swahili mihrab is also very present in many mosques of Oman, for example, in the Shawâdhnâ of Nizwa mosque, dated 1530 and decorated with an inlay of cut blue and white porcelain (Pradines 2011: 131–149).

From the fifteenth century onward, Swahili cities were surrounded by fortified stone walls, as notably at the Kenyan sites of Pate, Ungwana, Gedi, and Songo Mnara (Pradines 2004: 328–334). These urban fortifications support the centralization of the political power with local sultanates and reinforced the distinction between town and country, the coast, and the hinterland. The same dichotomy appears also in the emergence of a domestic architecture in stone differentiated from traditional African houses which symbolized hierarchy among the Swahili community. Only rich merchants and individuals from powerful lineages could live in stone houses. This social change is confirmed by anthropology and our observations in Gedi where architecture was profoundly altered at the beginning of the fifteenth century. Stone buildings became emblematic of the power of the *wa-ungwana* patricians/nobility and represented the very notion of the Swahili city (Fig. 4 and 5).

The genesis of the Swahili house is still subject to discussion, between supporters of a local evolution, including Mark Horton, Jeffrey Fleisher, and Stephanie Wynne-Jones (Fleisher and La Violette 1999; Horton and Middleton 2000: 119; Wynne-Jones 2016: 158–168), and those favoring exogenous influences, including Linda Donley-Reid, Abdul Sheriff, and Pradines (Donley-Reid 1990: 114–126; Sheriff 2002: 76; Pradines 2004: 111–112). According to Horton the use of coral stone architecture was first reserved for mosques, before becoming more widespread, being used for a group of large private houses in the fourteenth century. Mark Horton has argued for continuity in the evolution of Swahili houses, from traditional earth-built dwellings to large houses in stone, in terms of consistent traits in the plans of the buildings and in the use of space. Horton also asserts that stone architecture is a local invention reinforced by Fatimid technologies from the Red Sea. He cites multiple examples of architecture in coral limestone in the Dahlak Islands, Er Rih, Aydhab, and Suakin. However, this technology was not only found on Egyptian and Sudanese shores, with examples existing on the coast of the Hadramawt and in the Persian Gulf, in Bahrain, and in Qatar where coral blocks are called *hagar al-bahr*, or "stones of the sea." A further problem is the existence of very similar architecture in Yemen, the occupation of which by Indian merchants is confirmed by historical sources.

Archaeological excavations in Sanjé ya Kati demonstrate that the first stone houses were built with the same technology as the earliest mosques on the East African coast. The model proposed by Horton that first the mosques were built in stone then the Swahili adopted stone for their domestic architecture is not valid anymore. The coral *Porites* masonry was introduced in East Africa

Swahili Archaeology, Fig. 4 Pillar tomb of Kunduchi with Chinese porcelains, Tanzania

Swahili Archaeology, Fig. 5 Survey of the stone houses of Gedi (Malindi, Kenya)

by sailors, most probably from the Persian Gulf. Africans adopted this technology and material to create their own architecture, the Swahili architecture. The first stone buildings are recorded from the ninth to the tenth century in Shanga (Horton 1996: 224–242) and Dembeni (Pradines and alii 2015: 44–54). These buildings were made of simple undressed fresh sea coral blocks inserted in earthen walls. It was during the eleventh century that Swahili builders adopted coral *Porites* cut in small ashlars and set on regular courses to construct their mosques and their storehouses like in Sanjé ya Kati and Gedi (Pradines 2009, 2010: 27). These first buildings were very well made using exclusively dressed porite coral stones bounded with a very fine lime mortar. This technique was used until the twelfth century. But this technique was long and difficult to build many buildings; fresh porite coral blocks needed to be dragged from the shore during the low tide or for bigger blocks fished directly from the sea. The use of fresh coral was abandoned in favor of fossil coral limestone during the thirteenth century. This fossil coral limestone forms the geological substratum of the entire eastern coast. The blocks were taken from open-air quarries, not far from the construction site. The limestone was not cut in regular ashlar with horizontal courses as before, but rather constituted of small irregular blocks bounded in large masonry walls made with the rammed earth technique between wooden planks. Some walls were made of red mud and coral limestone like in Gedi (Pradines 2010: 111–157), and other walls were made of lime mortar and coral limestone like in Kilwa Kisiwani or Songo Mnara, for example (Pradines and Blanchard 2015, pp. 9–33). Fresh sea coral was still in use for fine sculptures around the *mihrab* in the mosques and the door frames and niches in large stone houses and palaces (Pradines 2010: 159–180). This technique was totally abandoned after the Portuguese occupation; the door frames, niches (vi-zidaka), and mihrab were done with thick stuccoes.

The plan of domestic Swahili architecture from the thirteen to the fifteenth century was strongly influenced by Indian culture. Two elements reflect the role of India in the genesis of Swahili habitations: the division of space into narrow, parallel rooms and the use of niches for wall ornamentation. Linda Donley-Reid (1990) identified three types of Indian house, which are very similar to Swahili habitations. The southern region of Gujarat, from Mumbai to Broach, exhibits houses with two or three parallel rooms and a lateral circulation zone. Women live at the back of the building, which has an exit separate from the main entry situated in the façade. Houses to the north of Gujarat, from Broach to Cambay, have three parallel rooms with a central passage. There is no door at the back, and the walls are decorated with niches in a style very close to that found in Lamu. The plans of the houses in Gedi are very significant: they present narrow, elongated rooms, all parallel except for one forming a side corridor (Pradines 2010: 125–157). Some rooms have symmetrically arranged niches in the walls. As just noted, the room layout and the wall decorations are characteristic of Gujarati dwelling. Houses in Shanga had similar niches during the fourteenth century (Horton and Middleton 2000: 118). These cavities were organized in a symmetrical fashion, with a balancing of space still found in Swahili houses today. From this we infer that the organization of central secluded rooms (*ndani*) and of niches in modern, traditional Swahili homes dates back to the fourteenth century. The origin of this form of niche comes from Gujarat and not from the African coast, as ornamentation with niches is found in Zabid and Mocha in Yemen, towns strongly influenced by Indian architecture from Surat. Niches found inside homes in Gujarat and Kutch obey a certain harmony, a regularity of space. This balance is based on symmetry of architectural elements. The plaster niches in Indian Bohras' houses are like miniature *mihrab*s; the alcoves, called *gokala*, are often associated with magical squares containing the name of Allah.

In the sixteenth century, many Swahili ports were abandoned by commercial traffic because of the Portuguese intrusion in the Indian Ocean. From the eighteenth century to the nineteenth century, the Arab presence led to a renaissance in Swahili architecture and urbanism. The towns gained height with multistorey buildings

influenced by South Arabian architecture from Yemen and Oman.

Future Directions and International Perspectives: Ports and Maritime Trade

Islamic archaeology in East Africa is strongly linked to navigation and trade in the Indian Ocean. International trade was at the center of Swahili society and was dependent on long-distance networks (Chaudhuri 1985). The port cities formed a link between the Africans of the High Plateau and the merchants of the Indian Ocean. The Swahilis were linked to the populations from the hinterland that supplied them with the products necessary for international trade and for the survival of their cities. The Swahili cities were, primarily, located at the mouths of rivers or of islands which formed good anchorages for ships. Positioned on the communication routes of deep-sea navigation and river cabotage, the Swahili cities used rivers as major thoroughfares to penetrate right in the hinterland. Communication between the coast and inland was effected by the rivers, and these waterways formed veritable corridors through the jungle and the bush. For example, the city of Mogadishu was dependent upon the Shabelle and Jubba rivers (Jama 1996: 28). In Kenya, the major rivers are the Tana connected to Mwana and Ungwana and the Galana connected to Gedi-Malindi. In the seventeenth century, the city of Pate had links with the Pokomo people who engaged in cabotage trade all along the Tana River in order to bring ivory to the city (Spear 1981: 82–85; Abungu 1989: 167).

The Swahili received manufactured goods produced in bulk and cheaply on the oriental markets. Nevertheless, firstly it is the exchange itself and the demand which determines the economic value of an object. This is why Swahili considered these objects as very valuable. Kilwa imported fabrics, and the inhabitants of Dembeni traded their rock crystal for Chinese and Islamic ceramics and glasses. More generally, the Swahili imported, in bulk, materials, ceramics, and glassworks and glass beads, which they used as money. In exchange they were exporting raw materials, but unfortunately, for archaeologists, these commercial products were invisible in that they were made of organic material, for example, leopards' skins, copal resin, ambergris (from the cachalot), mangrove wood, and tortoise shells. According to al-Masudi (Al-Masudi in Devic 1883: 179–188), the tortoise scales ("dhabl") were used to make combs, bracelets, and ornaments. Zeila was the port which handled the exports, although the scales came from the Comoro Islands and from the islands at the mouth of the Ufidji, no doubt the Rufiji and Mafia islands. According to the "Book of Wonders" (Sauvaget 1954: 189–309), the Waq-Waq people attacked the island of Qanbalû (probably Mafia) for its ivory and tortoise scales, and they also pillaged the islands located 6 days' travelling time away from Qanbalû, most certainly the Comoros Archipelago. Three other important products that were traded at the same time as ivory were gold, rock crystal, and slaves.

First of all, the slave trade formed an important part of African exportation. Ibn Battûta explained that the holy wars of Kilwa waged against the infidels were mainly aimed at finding slaves (Moffa 1995: 96–97), and not just domestic ones, they wanted slaves they could trade. Before the fifteenth century, most of the slaves came from Kenya and from the Horn of Africa where the ports of Zeila and Berbera were renowned for this merchandise (Freeman-Grenville 1963: 152). The amount of slaves exported to the Persian Gulf must have been very significant from early Islam as this led to the Zanj rebellion under the Abbasids. In 869, Ali ibn Muhamed al-Basri, the zaidite, managed to convince several hundred slaves to raise up against the central government, based at Samarra, by highlighting the injustice of their plight and promising them freedom and wealth. These black slaves were used to irrigate the land. The Zanj rebellion did not only involve black Africans, but brought together all the colored slaves and the Shiite minorities. Nicknamed Sâhib ez-Zanj, el-Basri proclaimed himself heir of the Shiites and fought for them against the Abbasids (Devic 1883: 160–166). The Zanj won several battles against the Khalif's armies, notably at al-Basrah, which they destroyed. This rebellion

was to last for 14 years, and al-Masudi teaches us that, apparently, it resulted in nearly 500,000 deaths. Thanks to the reinforcement of Egyptian troops, Vizier al-Muwaffaq quashed the rebellion in 883. The Zanj retrenched in their capital at al-Mukhtâra, in Lower Iraq where they were defeated and their leader executed.

Gold is undoubtedly the best-known African export. According to Muktahar ibn Tahir al Maqdisî, the land of the Zanj supplied a lot of gold to the Arabs, and this was the case from the tenth century. The extracted gold was sent to Sofala, a vassal of Kilwa Kisiwani as from the twelfth century. The gold was redistributed by Kilwa which thus ensured for itself a monopoly position until the fifteenth century (Mathew 1963: 112). In 1501, the Portuguese captain Cabral apprehended two boats from Kilwa which were full of gold (Freeman-Grenville 1962: 59–60). The commercial profits played a significant role in the prosperity of the Kingdom of Great Zimbabwe which exploited many mines (Beach 1980). The mining apparently began in the seventh century, and, in the beginning, it was probably in response to a regional demand.

Ivory was a major export of the Swahili coastline. Despite the competition with Asian elephants, it was the African ivory that the Indians and Chinese preferred. African ivory was considered superior in both size and quality. As specified by al-Masudi (Freeman-Grenville 1962: 15–16), ivory came from Africa and was normally exported to Oman toward India and China. This saddened al-Masudi because, without these market destinations, there would have been more ivory in the Muslim countries (Devic 1883: 179–188). Still in the tenth century, Al-Muqaddasi also speaks about the exportation of ivory to Oman, with Aden more likely receiving gold and slaves (Al-Muqaddasi, 1901: 51 and 147–148). According to the Cairo Genizah archives (Goitein 1966: 339; Bramoullé 2012: 131–135), the Jewish merchants traded in ivory, crystal, and ambergris in the cities of Aden and Kish. Included in the list of objects imported from India can be found Chinese porcelain, Yemenite soapstone, and African ivory. The ivory was worked in the countries of importation. Ernst Kühnel identified 60 ivories from Fatimid Egypt in the museums of Berlin, Paris, and Florence, consisting mainly of small engraved ivory panels, used as decoration on small boxes, furniture, thrones, and door frames. The Genizah archives (Goitein 1983: 38) provide lists of wedding trousseaux of the Jewish merchants which contained furniture with mother-of-pearl and ivory marquetry, indicating that ivory was not only reserved for the Fatimid princes but also for the upper classes. There is also a second group of small ivory objects dating from the beginning of the eleventh century, such as chess and backgammon pieces and dice. These small ivory kohl containers cost three dinars and were cheaper than the rock crystal bottles (Goitein 1983: 224). According to Contadini (Contadini 1998: 109–111), these small objects were carved from the offcuts of large objects.

Finally the most convincing elements of this early Islamic trade were found during the excavations carried out at Dembeni, on the island of Mayotte in the Comoros Archipelago. Dembeni is one of the oldest, largest, and richest Islamic archaeological sites in the Western Indian Ocean. Its apogee in the ninth–twelfth centuries was a period of intensive trade, first with the Abbasids in the Persian Gulf then with the Fatimid Caliphate in Egypt. Dembeni delivered an archaeological material of unprecedented wealth for the time, with a large amount of imported Chinese and Persian ceramics, as well as glassware from all over the Islamic world. This accumulation of richness was not made by chance, and during many years, archaeologists were seeking the origin of the wealth of this site. According to Pradines's excavations, the site at Dembeni appears to be a major distribution center for rock crystal in the Indian Ocean (Pradines 2013: 59–72). The fragments of rock crystal discovered are not from Mayotte, where the mineral is unknown, but were imported from Madagascar. The rock crystal was exported to Comoros together with other products, notably steatite

(or soapstone). The large island of Madagascar has long been recognized as one of the principal sources of natural crystal in the world, and this was probably the case from the Sassanian period. According to Horton the rock crystal was associated with the Fatimid period. This, in his opinion, was testimony of the Fatimid presence in East Africa via the Red Sea. The theory developed by Mark Horton (Horton and Middleton 2000: 79–80) is no longer valid and cannot be applied to the first centuries of Islam. Thus, if the Fatimids had known the geography of the African coasts very well (Rapoport 2014: 437–446), the merchants would not have been bypassing the Yemen where they had intermediaries and entrepôts plus the rock crystal was not coming from the Tsavo region (Kenya) but from Madagascar.

The rock crystal was imported to Mayotte from Madagascar in draft form and then exported to the capital cities of Baghdad (ninth–tenth c.) and Cairo (eleventh–twelfth c.) via Persian merchants who travelled with Omani boats and sailors (Pradines 2009: 49–73). On arrival in the island of Mayotte, the merchants exchanged ceramics and other items for the precious rock crystal, which only the best parts were retained. Arab and Persian written sources mentioned rock crystal from the islands of the Zanj in East Africa. According to al-Birûnî (973–1048) (Contadini 1998: 17–20), the crystal that was imported came from the islands of the Zanj. The port city of Basra was the main trading center during the Abbasid period and connected to the capital Baghdad from the ninth to the tenth century. In the middle of the eleventh century (1046–50), Nasir-i Khusraw spoke about the rock crystal sold at the lamp market to the old Cairo close by Amr Mosque (Bab al-Jawami). The el-Qanadil Souk was known for its rare and precious objects, such as tortoise shell small boxes and combs, enormous elephant tusks from Zangbar, and the most exquisite and expertly crafted rock crystal (Nasir-i Khusraw 1881: 149). This information was corroborated by the texts of the Jewish merchants of the Cairo Genizah. The crystal, known as Billawr, transited through Aden and on to the Yemen (Goitein 1983: 223–224). The products were then transferred and redirected toward the ports of Aydhab and Quseir on the Red Sea. The valuables were loaded onto camels and donkeys heading toward the Valley of the Nile and then transferred onto Fellucas in the direction of Cairo and Alexandria, where the rock crystal was finally worked on by expert craftsmen in the old Cairo called Misr-Fustat. The rock crystal was then shaped by skilled craftsmen to produce beautiful ewers and other Fatimid masterpieces.

The study of these exportations such as the rock crystal and the imports, in particular the ceramics, allows us to draw a new history of the Swahili coast and its contacts with other cultures of the Indian Ocean world. Even if the weight of African archaeology is still pressing over the Swahili culture, the recent researches provide new data on Indian Ocean trade and mark the coming of age of a reconnaissance of East Africa not as a periphery but as a center for Muslim culture studies.

Sweden: Cultural Heritage Management

Johan Hegardt
Department of Cultural History and Collections,
National Historical Museum, Stockholm, Sweden

Introduction

Heritage management in Sweden has a long history dating back to at least. This history can be viewed from two perspectives – continuity or discontinuity. The first perspective is the official view, but not without problems. When viewed as a continuing enterprise, heritage management becomes a heritage in itself. This keeps the power over heritage linked to authorities claiming long historical continuity, which conserves the management of Swedish heritage. I will therefore approach Swedish heritage management from the second perspective, namely, discontinuity. Viewed from this point, heritage management can be seen as contextual and dynamic and closely linked to an active society that has a need and desire for heritage because of political and social reasons. Heritage management in Sweden is the history of its legislation, of those institutions that have been and are responsible, and the country's position in a broader context, at first in a European context and later in a global context. Legislation is always related to moral and norms, to identity and being, to power and majority (Derrida 2005). Behind the explicit civic structures of heritage

Sweden: Cultural Heritage Management, Fig. 1 The Museum of National Antiquities, 1967. Social Democratic minister of Culture Olof Palme with scull of Stone Age "ancestor" in his hand. Palme later became Prime Minister and in 1986 he was assassinated on the streets of Stockholm. (Courtesy of Riskantikvarieämbetet. Image © Riksantikvarieämbetet)

legislation discussed here, a complicated and often hidden idea of ethnic continuity and identity can be found – the idea of a pure Swedish race and a united nation (Hegardt 2011a, b; Hegardt and Källén 2011; Svanberg in press) (Fig. 1).

Definition

Swedish heritage management can be classified into three historical contexts, Heritage as myth, Heritage as genealogy, Heritage as science and nation-narration, and a fourth – Heritage in a cosmopolitan world. Heritage is represented differently in each of these categories. Even the idea of Swedishness and a united nation is expressed differently, because of social, religious, and political needs and desires. Throughout history, many different institutions, academic subjects, museums, and authorities have been engaged in the management of Swedish heritage. The leading actor today is the National Heritage Board founded in the 1930s, but present legislation and centralized power is questioned and debated.

In 2005, I conducted a study with the department Sociology of Education and Culture at Uppsala University to find out who studies cultural historical subjects and heritage management related subjects at the different universities in Sweden (Hegardt 2005; Hegardt and Källén 2011). It turned out that the majority of the students came from native Swedish middle-class families with a desire for cultural capital. Finding a job in the heritage management system was the first wish for these students. This means, in short, that these individuals will reproduce and guard the narratives of Swedish heritage and history, because it is through these narratives that they gain their cultural capital and because they will do this inside a system organized by the State and civil society. The narratives thus become State governed and managed by people employed by the different authorities.

Swedish heritage spans over several millennia, starting with Stone Age remains dating back to at least 14,000 BP and ending in present-day industrial structures, for example. However, cultural heritage cannot be separated from nature and intangible and material cultural heritage exists within environmental contexts. Heritage thus becomes a metaphysical concept inscribed into structures, things, expressions, memories, and nature and has, because of this, been used and is used as a barrier against the outside world. Today,

Sweden: Cultural Heritage Management, Fig. 2 The Museum of National Antiquities, 1967. "Stone Age Swedes". (Courtesy of Riskantikvarieämbetet. Image © Riksantikvarieämbetet)

it, in a very problematic way, defines and encloses the Swedish and becomes a safe harbor in a dynamic world (Fig. 2).

Historical Background

Heritage as Myth: Seventeenth Century

Swedish heritage management has an ambiguous origin in the laws of the provinces from the fourteenth and fifteenth centuries (Swedish: landskapslagarna). Some of these laws settled what should be done with ancient objects found on someone's property (Jensen 2002). However, there existed no clear historical narrative connected to the laws or to the ancient objects and monuments. The point with these medieval laws was nevertheless to secure the present rather than to guard the past. In the mid-sixteenth century, Archbishop Olaus Magnus (1490–1557) stressed that ancient monuments should be preserved since they were constructed with the aim of commemorating the deceased or an important event (Jensen 2010: 153). In 1523, Sweden became an independent Protestant State after 500 years of Catholic governance, Danish oppression, and the Hanseatic League's control over the economy, according to established historical narratives. Being Catholic, Magnus was in a difficult situation. He had to connect himself to the new society with the help of ancient monuments and historical myths. (It did not help. He died in Rome.) For Magnus and others, heritage signified a mythological and heroic past, present in the landscape as symbols. The present past became useful in the political, religious, and social context of the time. In 1630, Johannes Bureus (1568–1652) was appointed Riksantikvarie (Custodian of Heritage). Being the first, he has had 29 successors up to present date, out of which two have been women. The first explicit heritage legislation was published in 1666. Sweden was a major imperial power in the Baltic region at that time, and myths of Swedish history are presented in thick volumes emphasizing patriotic perspectives and heroic narratives. The most bizarre of these was published in 1675

by Olof Rudbeck (1630–1702), claiming that Sweden was the lost Atlantis.

Heritage as Genealogy: Eighteenth Century

In 1753, Queen Lovisa Ulrika (1720–1782) founded The Royal Swedish Academy of Belles-Lettres with the purpose to encourage historical research, rhetoric, poetry, and the Swedish language. A few decades later, in 1786, King Gustav III (1746–1792) restructured his mother's Academy and moved Swedish language and literature to The Swedish Academy (later becoming responsible for the Nobel Prize in literature) (Jonsson 2003). The Riksantikvarie was linked to the new Academy, named The Royal Swedish Academy of Letters, History and Antiquities. A utilitarian approach, reason, and specialized historical research opened a new approach to heritage and history – genealogy and chronology. Historians such as Olof von Dalin (1708–1763) and Sven Lagerbring (1707–1787) questioned, together with a new generation antiquarians, earlier historians for not being scientific enough. The chronology of the nation and the genealogy of the King and the nobility became important. The legislation from 1666 was still at work and heritage was viewed as genealogical facts rather than symbols for a mythological and patriotic past.

Heritage as Science and Nation-Narration: Nineteenth Century and Early Twentieth Century

Sweden lost Finland to Russia in 1807, which was a traumatic blow to Swedish's self-confidence. The country was also in need of a new king. In 1814, Sweden gained Norway from Denmark, a great triumph. (Norway became an independent state 1905 and took with it an enormous amount of oil). During the nineteenth century, the Parliament obtained more power. The capacity to control and organize the society through civil servants had, however, been significant for Sweden since the mid-seventeenth century. Nevertheless, during early nineteenth century, new sciences such as archaeology, ideas of progression launched by German Enlightenment philosophers, such as Hegel and Kant, positivism and natural science, the idea that the nation is an ethnic and linguistic entity proposed by, for example, Fichte and Herder, contributed to chronological studies of Swedish heritage. An important boost was given to this process by the Dane Christian Jürgensen Thomsen's (1788–1865) publication of his Three Age System, featuring the Stone Age, the Bronze Age, and the Iron Age (Thomsen 1836). In the late nineteenth century, heritage management became centralized and related to bureaucratic institutions and museums in Stockholm, a process criticized by private actors in the provinces. The heritage legislation from the late sixteenth century was rewritten and will again be rewritten several times during the twentieth century to adjust to a changing society and centralized bureaucracy (Fig. 3).

Bror Emil Hildebrand (1806–1884) was impressed by Thomsen's museum and reorganized the Historical Museum in the university city of Lund after Thomsen's Three Age System. In the early 1830s, Hildebrand was called to

Sweden: Cultural Heritage Management, Fig. 3 B. E. Hildebrand, the grand old man of Swedish heritage management. (Courtesy of Riskantikvarieämbetet. Image © Riksantikvarieämbetet)

Stockholm to help Riksantikvarie Johan Gustaf Liljegren (1791–1837) at the Museum of Antiquities, a small museum in the Royal Palace. In 1837, Hildebrand was appointed Riksantikvarie and began to rework the museum following the same principles he used in Lund. In 1845, the Parliament decided to build a new National Museum and Hildebrand responded immediately with a memorandum (Hildebrand 1845) to the Academy explaining how the new museum should be organized. The National Museum stood finished in 1866 and the Museum of National Antiquities was placed on the ground floor. It followed Thomsen's ideas in detail, with the Three Age System as the main chronological principle. The galleries illustrated, like pictures in a book and in a proper chronological order, the progression of the nation. Narration was crucial when explaining how the nation has come into being through its heritage and Hildebrand and later Oscar Montelius (1843–1921) and Hildebrand's son Hans Hildebrand (1842–1913) never ceased to emphasize social and cultural progression. It was important to show a united people – one race – through prehistory and history. The museum would become the center for heritage management and archaeological research until the late 1930s.

However, already in the 1920s, the Museum of National Antiquities was bursting at the seams, being overfilled with objects. The bits and pieces of the nation coming into being, once glued together, were now slowly falling apart. At the same time, the Swedish society went through political and economical crises. According to Nina Witoszek (2002), these crises became a proof of temporariness, eliminating the idea of a secure and infinite historical process. To meet these crises, a welfare society – the folkhome – was introduced. Europe was viewed with skepticism as neofeudal, patriarchal, and unequal. Conflicts and tensions were to be avoided by the "imperative of harmony" and the society was to be built on rationalism, compromises, and consensus. According to Witoszek, Sweden from that time defined itself as the nation of goodness. Heritage management and the museums followed (Fig. 4).

Per Albin Hanson (1885–1946), the leader of the Social Democratic Party, introduced the welfare society and the "folkhem" (folkhome), and in the mid-1920s, Sigurd Curman (1879–1966) took over the Museum of National Antiquities, launching new museum policies and heritage politics based on the "folkhem." It was also decided that a new museum must be built, standing at the

Sweden: Cultural Heritage Management, Fig. 4 The Museum of National Antiquities, 1943. A place for consensus and compromise. (Courtesy of Riskantikvarieämbetet. Image © Riksantikvarieämbetet)

end of the 1930s. It was time to glue the bits and pieces of history back together again, this time on the principles of the folkhome, which was consensus, compromise, rationalism, and the society of goodness. To make this happen, heritage management and museums had to be reorganized. Until that time, the Riksantikvarie had been associated with the museum, but Curman introduced a new authority, the National Heritage Board (Riksantikvarieämbetet). The Board and the Riksantikvarie became responsible for the Nation's heritage, and the museum was made responsible for the collections of antiquities. The Academy was a third important actor (Fig. 5).

The Museum of National Antiquities worked with an advanced chronological perspective illustrating the united Swedes and how their special race came into being (see also Svanberg in press). In the 1920s and 1930s, these perspectives were emphasized and moved into heritage management under the authority of the Heritage Board. National consensus based on rationalistic epistemology became important, and heritage legislation and organization was founded on civic organization rather than on an explicit ethnic or linguistic principle. Nevertheless, the capacity of civic society to organize heritage is related to the ethnic and linguistic idea of a united Swedish race. Swedishness has been inscribed and narrated as heritage with the aim of guaranteeing stability and the homogenous nation, first disturbed when faced with cosmopolitan diversity and global economies in later decades of the twentieth century. Color consciousness (Appiah and Gutmann 1996) in Sweden is based on the idea that Swedes are a stable historical race of blond and blue-eyed people with a common heritage. Implicit racism is the outcome of such perspectives, becoming a

Sweden: Cultural Heritage Management, Fig. 5 Sigurd Curman in his office 1926. The painting behind Curman shows Gutav II Adolf, a seventeenth century hero King. (Courtesy of Riskantikvarieämbetet. Image © Riksantikvarieämbetet)

practical reality (if the Sami are not included) in the late twentieth century due to increasing immigration to Sweden. Through heritage and the "good" society, Swedes have viewed themselves as superior without having to face the people classified as inferior from a standpoint of a racialized discourse. When these "inferior" people suddenly turned up in Sweden as immigrants, Sweden has had to face itself, its history, and its idea of heritage. Swedish public-service authorities have rightly been accused of having profound problems with structural racism (de los Reyes and Kamali 2005; Pred 2000; Hegardt and Källén 2011).

Key Issues/Current Debates

The key issue for heritage management in Sweden since the early seventeeth century has been the definition of heritage as a state-controlled signifier of Swedishness, but without explicit narratives, heritage is rather pointless. Narratives produced by scholars in state-governed universities, academies, and museums have – through history – shaped the idea of a united nation, one people, and one race. The latest debate on archaeology and heritage management in Sweden has been published in Current Swedish Archaeology (Hansson and Källén 2010; Högberg and Källén 2011). Commercialization of contract archaeology and the relationship between heritage and a right-wing party that has come into parliament has been discussed. In both cases, it is the relationship between heritage and Swedishness, the historical continuity and authority of heritage management, the society as a stable united nation of one people and one race that is the crucial problem. The critical point made is that heritage management and archaeology can no longer build its existence on the idea of national continuity. The question is what to do. Heritage authorities, with their idea of a long historical continuity, the political parties, and the parliament, have few answers to the problem. Yet, heritage as a national and ethnical signifier has shown to be both obsolete and dangerous (Hegardt 2011c).

International Perspectives

As mentioned, Swedish heritage management, archaeology, and the legislation is under pressure in a changing world. Immigrants and cosmopolitan movements play their parts, but a more open Swedish society, the market economy, and political and economical crises have been influential as well. Continuity and Swedishness does not work in a society marching into a global world with cosmopolitan responsibilities. The uncertainty that has followed has opened for right-wing parties, but also for other political groups, local organizations, museums and authorities, and the public to appropriate heritage in line with the old idea of historical continuity, a united nation and Swedishness, and building their arguments on traditional heritage narratives, for example, by replacing the word race with the word culture and striving to enclose Sweden, regions or local areas through its heritage.

Future Directions

Heritage management in Sweden must find a new definition of what it means to be Swedish. From my point of departure, the word "cosmopolitan" (Appiah 2007) describes the situation best. If one looks closer into what is called Swedish heritage, one finds that only a small part of it can be defined as Swedish in accordance with the national definition of the word. Material heritage has been brought to Sweden from all parts of the world by people from all parts of the world. Historical buildings and other structures have been built by workers and paid for by wealthy people who have come from all parts of the world. Intangible heritage is a consequence of people meeting with people from many parts of the world. Every museum in Sweden is filled with objects that strengthen this perspective. What is needed is a definition of being Swedish that expands the boarders of the nation-state, perhaps in line with Bhabha's (2004) ideas of hybridity. Nonetheless, true and authentic Swedishness and heritage only exists inside a very narrow and imagined construction, and as

Appiah (2007) has stated it: Cosmopolitanism is not hard work, repudiating it is.

Swedish Institute of Classical Studies at Rome

Barbro Santillo Frizell[1] and Simon Malmberg[2]
[1]Svenska Institutet i Rom, Rome, Italy
[2]Department of Archaeology, History, Cultural Studies and Religion, University of Bergen, Bergen, Norway

Basic Information

The Swedish Institute of Classical Studies at Rome (Via Omero, 14, 00197 Rome, Italy, http://www.isvroma.it) is a research institute devoted to classical studies with a special emphasis on archaeology. It is the base for Swedish archaeological excavations and academic activities in Italy. In collaboration with Swedish universities, the Institute gives annual courses in classics, art history, and related subjects. The Institute is located in central Rome and has a research library with c. 60,000 volumes. Twenty guest rooms and apartments are at the disposal of visiting researchers and holders of scholarships. The Institute is a state-financed foundation, with its board and secretariat situated in Stockholm, Sweden. The Institute's activities in Rome are supervised by a director educated in classics and a vice director trained in art history.

Major Impact

History, Facilities, and Activities of the Institute

The Institute was founded in 1925 on the initiative of Swedish Crown Prince Gustav Adolf (1882–1973), who was a professional archaeologist with a special interest in classical studies. As King Gustav VI Adolf, he maintained his interest in the Institute's activities, not least the archaeological excavation projects, and his lifelong commitment has been of the utmost importance to the institute.

The original aim behind the foundation of the Institute was to enable Swedish university students, and teachers in classical languages, to study the ancient topography of Rome and Italy, as well as the art and monuments of the same. A main objective of the Institute has always been its educational activities, as manifested in annual courses given to students from Swedish universities. These include courses in archaeology (offered since 1926) and in art history (offered since 1959), as well as other, more temporary, courses.

The Institute awards annual scholarships to support major research in Rome during the academic year in the subjects of architecture, art history, archaeology, philology, and conservation and heritage research. Thanks to a donation from Fondazione Famiglia Rausing, the Institute has broadened its research in other humanities as well, such as the Italian language, comparative literature, social anthropology, history, and the aesthetic disciplines.

The library is primarily devoted to archaeology, classical studies, and art history. The publication series Acta Instituti Romani Regni Sueciae was founded in 1932, and in 1992 the series Suecoromana, specializing in art history, saw the light. Since 2004 the Institute also possesses an on-line publication series, called Projects and Seminars. In collaboration with the Swedish Institute in Athens, the Institute publishes an annual journal called Opuscula.

Since 1940 the Institute has been located on Via Omero 14 in the Villa Borghese Park in Rome, in an area nearby several other international

institutes. The Italian government placed the site at the disposal of the Institute for free, on condition that Sweden make the grounds available for the Italian Cultural Institute in Stockholm. The Institute building was designed by the famous Swedish architect Ivar Tengbom (1878–1968), while several distinguished Swedish designers and artists were responsible for the furniture, textiles, and works of art that furnish the Institute. A new guest wing was added in 1964, an auditorium in 1988, and a new library wing in 2008.

Archaeological Research

The Institute has since its foundation been devoted to the study of Italy's ancient cultures. The research undertaken may be generally divided into following areas: Italic prehistory, Etruscan culture, the topography of the city of Rome, Pompeii, landscape studies, and the cultural heritage of Mediterranean antiquity.

The study of central Italy's prehistoric cultures, primarily the Etruscan and Latin cultures, has long been at the center of the activities of the Institute. The first Swedish excavation in Italy took place in the Latin town of Ardea south of Rome in the 1930s. The period after World War II saw a dramatic increase in the archaeological activity of the Institute, with important excavations in the Etruscan towns of San Giovenale and Acquarossa and the prehistoric site of Luni sul Mignone, in the years 1956–1978, with the aim to explore settlement patterns in Etruria. Moreover, in the 1970s, a joint Nordic excavation was carried out at Ficana south of Rome. Since then, more limited fieldwork has been undertaken, primarily in the form of surface survey and aerial photography.

The Institute also has pursued research on the ancient city of Rome and its hinterland. An important study of the Republican city wall of Rome was followed in 1939–1954 by excavation of the earliest phases of the Forum Romanum and, in the 1980s, by a joint Nordic exploration of the Temple of Castor and Pollux in the Forum Romanum. Other archaeological projects have focused on documentation and survey by nondestructive methods, complemented in some cases with limited excavation. Fieldwork of this character has been done at San Lorenzo in Lucina and the Lateran Baptistery in central Rome and at the imperial villa at Prima Porta on the outskirts of Rome. In the city's hinterland, joint Nordic excavations were undertaken at the imperial villa at Lake Nemi. The recently concluded research project Via Tiburtina studied the road with this name between Rome and Tivoli. It was an interdisciplinary project involving architecture, urban planning, archaeology, history, art history, and conservation and cultural heritage which contributed new perspectives on communication, cultural history, as well as urban and suburban development from the Bronze Age until modern times.

Since 2000 the Institute has pursued an archaeological project at Pompeii, aiming to analyze and comprehensively document a residential block, Insula V 1. Previously excavated and non-published areas are being documented and systematized to make this information available in a new publication and on-line (www.pompejiprojektet.se).

In recent years, the Institute has been focusing more on questions concerning cultural heritage and classical reception. Within this area, research has been undertaken on the preservation, dissemination, and understanding of ancient remains and cultures in modern society.

Sweet Potato: Origins and Development

Adelia C. Bovell-Benjamin
Department of Food and Nutritional Sciences, Tuskegee University, Tuskegee, AL, USA

Basic Species Information

The botanical name for the sweet potato is *Ipomoea batatas* [L.] (Lam). The most common indigenous names for the sweet potato tuber in Central and South America include *batata*, *boniato*, *camote*, *batata doce*, and *apichu*. From Peru, Hawaii, and Samoa to the Philippines, sweet potato is known by a broad range of cognates: *kumar*, *uala*, *umala*, and *kamote*, respectively. The sweet potato is called *kumara* in New Zealand. Eastern Africans know the sweet potato as *cileraabana*, "protector of the children," and it is called *ubhatata* in South Africa. It is known as *kara-imo*, "Chinese potato" in southern Kyushu, and in most other parts of Japan, it is known as *satsuma-imo*, "Japanese potato."

Timing and Tracking Domestication

The sweet potato is considered to originate in the New World, although its precise origin is not well defined. Archaeological remains of the storage roots, or tubers, of sweet potato show it was long used as a food source by the inhabitants of Peru. Preserved remains and samples from ancient tombs and burial sites have yielded cloth tapestries and ceramic vessels that occasionally bear woven images and artistic representation, respectively, of the sweet potato (Sauer 1951). Steinhold (2008) states that Peruvian sweet potato remains date back to 10,000 years ago in South America. Towle (1961) reports that dried sweet potato roots have also been found in more recent grave sites at Ocucaje dating to CE 1–600. Alternatively, Austin (1988) proposed a more eastward origin for the sweet potato between the Yucatán Peninsula of Mexico and the Orinoco River in Venezuela.

The sweet potato was domesticated roughly 10,000 years ago in a period when environmental and climatic conditions were completely different to today. During the early postglacial period, several factors, including increasingly arid climate and decreased natural resources, influenced the change from hunting and fishing to the planting of food crops. This intervention led to the domestication of the wild species of sweet potato by humans.

Commercial cultivation of sweet potato began in Hawaii in 1849. However, Asia is now the largest sweet potato-producing region in the world, with an annual production of 125 million tons. China produces roughly 80% of the world's sweet potato (117 million tons annually), making it the leading supplier of sweet potatoes in the world. Latin America and North America produce about 1.9 million and 600,000 t annually, respectively.

Today, the sweet potato is a staple food source for many indigenous populations in Central and South America, Ryukyu Island, Africa, the Caribbean, the Maori people, Hawaiians, and Papua New Guineans. The sweet potato contains many nutrients including protein, carbohydrates, minerals (calcium, iron, and potassium), carotenoids, dietary fiber, and vitamins (especially C, folate, and B_6); it contains very little fat and sodium. The chemical composition of the sweet potato varies greatly according to genetic and environmental factors. Protein contents of sweet potato leaves and roots range from 4.0% to 27.0% and 1.0 to 9.0%, respectively. The root has high concentrations of anthocyanin and β-carotene.

Botanical Classification

The sweet potato is a creeping dicotyledonous plant with the following systematic classification (Huamán 1999):

Kingdom: Plantae
Division: Magnoliophyta
Class: Magnoliopsida
Order: Solanales
Family: Convolvulaceae
Tribe: Ipomoeae
Genus: Ipomoea
Subgenus: Eriospermum
Section: Eriospermum
Series: Batatas
Species: *Ipomoea batatas* (L.) Lam.

Within the Series Batatas, there are 13 wild species, which are considered to be related to the sweet potato (Austin and Huamán 1996). The number of chromosomes in the sweet potato plant is $2n = 6x = 90$, indicating it as a hexaploid plant with a basic chromosome number $x = 15$. Although the Series *Batatas* constantly undergoes revision, it contains roughly 12 other species, which are predominantly diploid ($2n = 2x = 30$) and a few tetraploids ($4x = 60$), which are wild.

Polyploid species are *I. cordatotriloba* with 2x and 4x and *I. trifida* with 2x, 3x, 4x, and 6x (Huamán and Zhang 1997).

There are diverse theories regarding the evolution of *I. batatas*. For example, Japanese researchers have considered it an autopolyploid derivative of *I. trifida*. On the other hand, American researchers posit an allopolyploid origin involving *I. trifida* and an unidentified tetraploid parent (Collins 1995). Zhang et al. (1998) suggests northern Peru and southern Ecuador as a secondary center of sweet potato diversity for *I. batata*s. Other important centers of diversity exist in sub-Saharan Africa, Papua New Guinea, and Indonesia. The geographic distribution of the wild species of Series Batatas is within the Americas, with the exception of *I. littoralis*, which is found in Australia and Asia. The cultivated species *I. batatas* includes plants that are very variable in their morphology.

Currently, thousands of cultivars are grown throughout the world and are unique to countries or to smaller regions within countries. All cultivars are more or less sweet flavored. Sweet potato cultivars exist in many colors of skin and flesh, ranging from almost pure white through cream, yellow, orange, or pink, to a very deep purple. For example, white- to cream-colored flesh sweet potatoes are common in the South Pacific, Africa, the Caribbean, and most other developing countries. In contrast, sweet potatoes commonly consumed in the developed countries, normally have yellow to orange flesh. The commercial sweet potato varieties in Hawaii have white, cream, purple, and yellow to orange color flesh.

The sweet potato is among the world's most important root crops today, especially in the developing world. Information on its archaeology, distribution, and genetic variations in ancient times has given scientists a better understanding of how this crop evolved under the selective and protective influences of human.

Switzerland: Upper Paleolithic Living Floor Investigations

Denise Leesch
University of Neuchâtel, Neuchâtel, Switzerland

Introduction

Upper Paleolithic living floors represent moments in the life of hunter-gatherers in the form of scattered finds and ephemeral features. Such sites are naturally vulnerable to later activities and well-preserved examples are rare.

Key Issues/Current Debates/Future Directions/Examples

Investigating how such a site was composed is primarily achieved by fine stratigraphic observation and later by refitting of the recovered flint artifacts, bone fragments, and fire-cracked rocks. The network of lines created by conjoined pieces whose location is recorded three dimensionally allows us to visualize intra-site dynamics and to establish the relative chronology of a site's use. Further crucial information on the time depth of an archaeological horizon is obtained by studying the period(s) of the year during which a site was occupied. Special attention is therefore paid to screening the excavated sediments in order to recover all fragile organic elements that may be used for season determination, notably the teeth from very young animals, less than one year old, and the remains from small hibernating mammals such as ground squirrel and marmot. Another major concern is to differentiate anthropogenic structures (e.g., pits and post holes) from natural features dug by burrowing animals (e. g., collared lemmings or narrow-headed voles). Similarly, it is important to correctly identify naturally accumulated stones or other geological phenomena that may evoke human-made structures. For that reason, the horizontal view of a living floor, however impressive it may be, needs to be completed by detailed

Switzerland: Upper Paleolithic Living Floor Investigations, Fig. 1 The Magdalenian open-air site Monruz (Neuchâtel, Switzerland). The living floor yielded more than 40 well-preserved hearths and remains from at least 56 horses. The layer, though only c. 2–3-cm thick, has proved to be the result of repeated occupation episodes after successful horse hunts. (© photo Y. André, Office et Musée d'archéologie Neuchâtel)

stratigraphic documentation of all structures and features observed on the surface.

Hearths are of special interest because they acted as focal points around which most of the technical, domestic, and social activities took place. In the vast majority of sites, however, charcoal has been destroyed and the soil shows no traces of heat action, thus making it difficult to precisely locate the combustion areas and other hearth-related structures. The approximate position of the hearths is then endorsed by confronting the spatial distribution of all thermally altered objects, notably flints, bones, and stones. In the rare cases of hearths still containing black sediment, the residues are screened separately in the laboratory and sorted under the microscope in order to extract all discrete remains such as charcoal fragments, charred seeds, bones, and fish scales, relevant for reconstructing the use of the hearths.

An exceptionally well-preserved Magdalenian living floor excavated in Monruz, at the edge of Lake Neuchâtel (Switzerland) in advance of motorway construction, offers an example of these techniques in action. The floor belongs to an open-air living and processing site dated to c. 15,500 years ago. Due to high stratigraphic resolution, it was easy in this case to follow the micro-topography of the thin covering layer (c. 2.5-cm thick), so exposing the intact living surface at the very moment of its abandon (Fig. 1). Since the detailed distribution of finds and features is of paramount importance, it is necessary to avoid treading on the excavated surface: excavators work from platforms supported by scaffolding (Fig. 2). Dense bone and flint scatters, together with extended patches of red ochre, were associated with more than 40 hearths of various types and dimensions (bowl-shaped and flat structures). By refitting several thousands of fractured stones, it could be demonstrated that all had been originally brought onto the site to cover hearths, so conserving heat – a combustion system characteristic of the Upper Paleolithic period. At that time, fuel was scarce and included only twigs of wood species, such as dwarf willow and dwarf birch, that grow low to the ground. By placing stones on top of the brushwood, the use of the hearths slowly released the heat they had accumulated during the short combustion phase. Stones that fractured in the heat were subsequently dispersed. Through precise mapping of the activity areas, it could also be demonstrated that most of the hearths were of multifunctional character. Maintenance of hunting weapons was

Switzerland: Upper Paleolithic Living Floor Investigations, Fig. 2 In order to not disturb the original position of the finds, excavation of Paleolithic living floors is operated from a slightly elevated platform made from planks. The sediments are filled into buckets to be wet-sieved per ¼ of square meters, a well-adapted spatial unit for interpreting even discrete find scatters. (© photo Y. André, Office et Musée d'archéologie Neuchâtel)

Switzerland: Upper Paleolithic Living Floor Investigations, Fig. 3 Model of dwelling units based on the location of the large pit-hearths and charcoal scatters (Leesch and Bullinger 2012, Fig. 11)

systematically performed less than 50 cm from the heat source, and sewing, as shown by the fractured bone needles, less than 1 m away. Hide treatment, probably because it required more space, took place at a slightly greater distance from the hearth. With the focus on the larger hearths, it was possible to propose living units within the overall pattern of debris (Fig. 3).

The Magdalenian site of Monruz is interpreted as a site that was occupied repeatedly following successful horse hunts. During each hunting event, only one to a maximum of three horses was killed. After the hunt, the whole group moved from its former camp location to this point where the horses were butchered and consumed. According to the number of killed animals, the occupation lasted for one to a few weeks. While staying at this place, diverse smaller species such as ibex, marmot, alpine hare, and various birds and fishes were hunted in the surrounding area and brought to the camp where they were processed and eaten in the immediate vicinity of the fireplaces. No more than three large hearths functioned simultaneously. Thus, what appeared at first sight to represent a single-occupation level was shown by careful excavation to correspond to a palimpsest created by repeated short habitation episodes during spring and summer.

So perfect an Upper Paleolithic picture did the Monruz deposit provide that part of it was extracted as a single block and removed out of the path of the motorway. It was enclosed in a container made from metal sheet piles and underlain by large pipes filled with concrete (dimensions of the block: 11 × 6 m × 2.5 m; weight: 400 t). The "box" was then loaded onto the platform of a trailer and taken to a new location where it could be studied without time constraint (Fig. 4).

Symmetrical Archaeology

Christopher Witmore
Classical and Modern Languages and Literatures, Texas Tech University, Lubbock, TX, USA

Introduction

If archaeology is the study of things with an aim to understand pasts and their relevance for life, then the addition of the adjectival qualifier "symmetrical" constituted a provisional step to help render it so. With its popular definition as "the study of the human past through its material remains," archaeology relegates its objects to the subordinate position of means and bestows upon its ends a spurious precedence, ultimately denying those throngs of ceramic fragments, hand axes, wall foundations, buried road surfaces, or rusty sardine cans their role as protagonists. Without things, any understanding of past worlds would be impossible (Olsen et al. 2012). And yet, the common definition of archaeology limits its objects to the status of mere vehicles. Symptomatic of this overly reductive, end-oriented (telocentric) definition are a series of compulsory disclaimers, sounded throughout the field's history, to remind practitioners of the need to reach beyond the thing itself. If the words of Mortimer Wheeler (1954, v) – "not *things*, but *people*" – or Robert Braidwood (1959, 734) – "the Indian behind the artifact" – took on mantric hues within archaeology, then it was because they encapsulated the habit of consecrating that modern fiction of a humanity without things within an elevated echelon of reality. Symmetrical archaeology began as a modest proposal to remember those increasingly neglected nonhumans consigned to the wings as props for humans among themselves, what archaeological practitioners viewed as the privileged participants within those "meaning-laden," "social" spectacles that must have comprised past worlds (Olsen 2003).

Of course, just as there is more to the marginalization of the nonhuman than a question of emphases, there is more to symmetrical archaeology than a rescue operation on behalf of nonhuman things. Beyond desperately simplified bifurcations of the world into subjects and objects or cultures and nature, there is a broader tendency to view humans as dominating the pliant substratum of objects which passively accepts its lot. Such a pathos opens archaeology to a fundamental expressive fallacy – the presumption of a human agency behind objects rendered from the angle of material memories encountered in the present (Olivier 2011; Olsen et al. 2012; Witmore 2014). Symmetrical archaeology aims to safeguard practitioners from such prejudicial reasoning by reinjecting a measure of analytical agnosticism. So long as ontological distinctions are doled out to specific kinds of entities in advance, one will remain blind to the long roster of objects – oak trees, goats, ox-pulled plows, flash floods laden with debris, or backhoes – that make a difference in the formation of the archaeological record.

What once seemed to be an ineluctable gulf between science and the humanities was scoured out through a taxonomic tendency to sort entities into two separate realms (for a renewed assertion of such an ontotaxonomy, see Nativ 2018). Azotobacter and water-logged cypress wood, phosphate concentrations, buried soils, animal bones, and carbonized seeds were consigned to the natural sciences, while throughout the humanities humans were regarded as fundamental ingredients to be found in every situation (Harman 2010, 146–147). Those who assume rapports between stonemasons and the Phonias tower to be of a *sui generis* variety, while placing into a different caste those relations between the storm-infused river and the structure's foundations (leading to its partial collapse in 2017), continue to reinforce this melodramatic scheme (Fig. 1). Rather than arbitrarily elevating humans among themselves to a privileged position in relation to nonhumans from the start, a symmetrical archaeology recomposes all beings as entities among other entities. The principle of symmetry does not imply that all entities exist equally – asymmetries are legion – rather, it humbly suggests that all entities equally be granted dignity as concrete and autonomous *things* at the outset

Symmetrical Archaeology, Fig. 1 Phonias tower and river in 2018

of any analysis (Olsen and Witmore 2015; Witmore 2014).

Symmetrical archaeology is often incorrectly assumed to constitute a full-blown theoretical platform, a replacement for post-processual and contextual archaeology (cf. Wallace 2014). But symmetrical archaeology doesn't provide any applicable theory. It simply offers a series of propositions for approaching abandoned bastions or buried corridors. It embraces a disposition to care for ancient olive trees or disused oil presses. It aspires to generate more faithful, more inclusive, accounts where things – what hold suggestions of their pasts – are recognized as mediators over mere intermediaries. It recognizes pasts not as separated off from any present by ruptures or revolutions (something reinforced by an image a linear, successive, and externalized time), but as lingering amidst perishing, gathering amidst dispersion, and enduring amidst transformation within a dynamic ecology of coextensive, actual entities. Associated with symmetrical archaeology is a shift from questions of epistemology, "what this awl means," to questions of ontology, "what this awl is." While this line of questioning does not imply, as it is often assumed, that symmetry is an ontological maxim, it should be stressed that pressing questions in terms of the ontological grounds of archaeology constitutes a longstanding aspiration of the field (Clarke 1968).

Symmetrical archaeology eschews that critical gesture of dialectical upheaval where other practices, concepts, or questions are ousted to the realm of the outmoded (González-Ruibal 2007). It avoids that disciplinary amnesia associated with a paradigmatic image of progress. Rather than exaggerating differences with other subdisciplines, symmetrical archaeology excavates to what is common for archaeologists everywhere – *things* (Olsen et al. 2012). If a one is to dispense with ready-made categories which obscure and betray what things suggest then one cannot begin by seeking out relevance, political or otherwise, for their objects of study as a starting point. Our fidelity begins with the object at hand which makes a difference in a given situation. At the start, symmetry reminds us that nothing should be excluded due to arbitrary hierarchies of value or preformed dogmas concerning the nature of the real.

To deny a carved rock surface, the position of vehicle in social relations among Scandinavian

hunters is neither to dismiss the possibility of the memory that the rock surface holds nor to reject its importance to erstwhile groups in the past. Symmetrical archaeology submits that any description of what was, or what might have been, should be put at risk in light of what of things themselves suggest. For symmetrical archaeology, any account that aims to disclose suggestions of the past should remain open to surprise and uncertainty. In this, thick description cannot be severed from explanation (*pace* Barrett 2016, 1683), for an account unfolds in the course of engagement whereby things reveal something of themselves. If abandoned surfaces cannot be reduced to an erstwhile equestrian barrack, animal enclosure, or ruin, then painstaking work must be done to explain one in terms of the other. In order to connect a portion of polygonal walling to the psychopolitical well-being of a Hellenistic polis, significant labor must be invested and this work is always open to reassessment.

Symmetry and Asymmetries

Symmetry is a key proposition at the heart of a symmetrical archaeology. Looking back to its formulation as a principle in David Bloor's *Knowledge and Social Imagery* (1991[1976]), symmetry offered a way of understanding both rationality and irrationality, truth and falsity, and success and failure in the same terms. Whereas this first principle of symmetry operated within the exclusive realm of society, Bruno Latour's generalized principle of symmetry sought to breach the so-called great divide of culture and nature, and harness the same principles of explanation for both humans and nonhumans (1993). After Latour, agency cannot be monopolized as an exclusive capacity of millers, for it may belong to stream channels, grinding stones, and grain. After Latour, self-affirmation should not be restricted a priori to priests of the Delphic oracle, for it may be a characteristic of the stylobate, Doric columns, and cella walls of the temple of Apollo. One now not only has to be prepared to speak about humans and nonhumans in the same terms, but also acknowledge how woefully disingenuous it is to make an attempt at disentangling reality into only two types of entities at the expense of others.

Whether one is concerned with better descriptions of archaeological practice, the astonishing stability of the archaeological record, or the formation of the Argive polis, a generalized principle of symmetry is at most a disposition meant to remind us not to decide in advance what role concrete entities play in a given situation by subsuming them to interpretive schemes or melodramatic abstractions. Rather, symmetry injects a level of agnosticism from the start. To embrace a learned ignorance is neither to avoid a story concerning past worlds nor evade questions of meaning, but rather to put archaeological accounts at risk in light of what things suggest concerning *their* pasts. To state it another way, the solution for what a thing may, or may not, have been should not drive its realization. An archaeologist cannot begin with the answer that a series of wall foundations under excavation at Binchester was a barrack block for an auxiliary cavalry unit. To approach these objects as the Roman past from outset is to cede to oblivion what becomes of a former barrack as an erstwhile animal fold, quarry or grass-covered mound of tumbled stone. To begin with what was, is to disregard what has become of it – things that hold memories of other pasts (Olivier 2011; Witmore 2013). Only by suspending the solution, which relates to a classic issue of assumed versus justified identifications for archaeological objects, can we ultimately better serve our ends.

If a weakness of the term "symmetry" relates to the fact that it cannot be taken too literally – that is, as an erroneously simple balance in the distribution of people and things or a misguided sense of equivalence in the values we accord different entities – then its strength rests upon its awkwardness as a proposition upon which one should place no empirical weight. Thus, to be symmetrical is not to champion mutual exchange, balanced co-living, or reciprocity between all entities, but to remain open to such a possibility without declaring dependencies in advance (*pace* Hodder 2014). Herein lies a common reaction to symmetrical archaeology, which is seen as eschewing

questions of power – indeed, Latour's own work is often lambasted for its supposed indifference to morality and politics (e.g., Van Dyke 2015). Yet such patent misreadings or misunderstandings miss the whole point of symmetry, which is to find power lurking in places one would not have otherwise looked. By withholding the melodrama of politics as first philosophy and the improbable position of always being right, by avoiding spurious and deceptive attempts to shift emphasis elsewhere, and by taking leave of dialectical conflicts that always attempt to fight power head on with power (Webmoor and Witmore 2008), symmetrical archaeology invests in diplomatic parleys that root through the hidden recesses of influence and inequity so that another path may open.

To be symmetrical is not to foreclose on asymmetries, which are pervasive, but to better root them out. One might assume asymmetries to have existed between German soldiers and PoWs at the coastal bastion of Svaerholt. And yet by placing such assumptions aside one begins to gain a sense of what alcohol bottles, smoking pipes, and pipe cleaners within the camp suggest: some deviation from expected behavior was accepted among those on either side of the fence (Grabowski et al. 2014). Exchange and sharing seems to have occurred; perhaps in being dependent on each other, they developed a sense of sympathy. Such hesitation also leads one to ponder an even larger asymmetry whereby all these foreign immigrants, PoWs and soldiers alike, shared a common fate as prisoners to a distant cape in the high-arctic; a land of harsh weather conditions under the alteration of protracted light and protracted dark.

Initial work under the colors of symmetrical archaeology drew heavily upon actor–network theory with its emphasis on imbroglios/mixtures of humans and things, with its overemphasis on action at the expense of other qualities of objects (also see Watts 2007; Whitridge 2005). Many of these early examples (i.e., Olsen 2003; Witmore 2007) remained asymmetrical by placing more emphasis on relations, assemblages, and entanglements at the expense of the being, autonomy, and integrity of things. Yet, unlike Latour's symmetric anthropology, symmetrical archaeology eventually took the additional step of conceiving of a thing's relations and autonomies in symmetric fashion (Olsen 2010). One must be prepared to speak of a ceramic jug *in-itself* and a ceramic jug *for us* or *for others* with equal favor. In other words, a generalized principle of symmetry demands that we also do not decide in advance whether an object's relations, actions, or effects should be elevated over its own idiosyncratic being (see Harman 2014, 41). It would make little sense to undertake archaeological research if our objects were a priori entangled in their pasts, if they already pointed beyond themselves to other things. It takes substantial work to articulate connections between objects, which can only provide hints as to their erstwhile rapports. Archaeology requires a trust in things to reveal something of themselves and in its own practices to disclose more than what is immediately given over in experience. Archaeology requires significant effort to apprehend something of its objects' pasts along with the creativity and imagination to piece together a story of what might have been, however tenuous it may be.

Approaching Things

Symmetrical archaeology initially regarded things, according to Bjørnar Olsen, as "those enormously varied physical entities, … [as] beings in the world alongside other beings such as humans, plants, and animals" (2012, 212; also 2003, 88). Positive emphasis was placed on "thing" in its etymological sense stemming from the German root "ding," a "gathering," "assembly," or "matter of concern" (Olsen 2003). An internal combustion engine is a gathering of achievements executed centuries and even millennia earlier in far off lands by anonymous strangers among other things – consider the flywheel and the potter's wheel of ancient Egypt or the camshaft and fifteenth century forges driven by vertical waterwheels (Dartnell 2014, 201–206). The ancient Greek polis of Argos is a heterogeneous assemblage of open spaces for mutual coexistence; specific areas for assembly; pride-engendering architectures and exhibitions

of esteem-inducing objects; abodes for favored gods who might or might not return their favor; accommodated citizens with their houses and households; protective walls; media holding otherwise fleeting words and archival repositories; an infrastructure of streets, roads, and paths; an encompassing territory; and much more (Witmore 2017a). The superfund site of the Jackpile-Paguate uranium mine is a common matter of concern for the community of Laguna Pueblo, the Environmental Protection Agency, and the Atlantic Richfield Company – for some, it is a radioactive wasteland requiring constant monitoring and containment; for others, it is the largest open-pit uranium mine in the United States, holding vast stores of untapped uranium; and yet for others, it is a dark site of erstwhile labor and loss in the midst of an ancestral homeland (Kuletz 1998, 19–37). Still, any definition of things alongside other entities remained a taxonomic formulation so long as it specified ontological differences between various kinds of entities in advance.

To speak of things or objects for a symmetrical archaeology is not to speak of things in opposition to people, or objects in contradistinction to subjects. To speak of things or objects for a symmetrical archaeology is not to invest in an ontotaxonomy of bifurcation true to a purified partitioning of the world into different kingdoms – one occupied by transcendent humans, the other by languid objects. Both things and ideas have to be dislodged from that old sorting of the world into abusively reductive dualities of humans and the rest. But to recognize models of state formation and Teotihuacan as equally things is to leave aside those old assumptions and arguments that regard empirical engagements with walls on the ground as more archaeological than abstractions concerning how those walls came to be situated around a gigantic ceremonial center. Practical exploits tend to abuse things as much as theoretical concerns (Harman 2011; Webmoor 2012). Whether an engagement with walls or a model of state formation is better or worse will rest entirely on the object itself and the purposes for which serves a given archaeological engagement.

Thus, things are not, as Leo Stein had it, "what we encounter," to be distinguished from ideas, "what we project" (Brown 2003, 11). Utopian dreams of the ideal state, ruined aqueducts, the cow-eyed goddess Hera, turf embankments, thunderbolts, centaurs, porcelain plates, Pausanias's *Periegesis Hellados*, riparian deposits, plane trees, lithic scatters, drift beaches, goats, Roman auxiliary units, and shovels are all equally things. This litany should not be read as an appeal to an undifferentiated world. All entities are placed a priori upon the same footing as *things* without presupposing arbitrary ontological distinctions. From this ground, it follows that things should be allowed to define themselves, to assert their differences, their otherness, however subtle. One has to respect the integrity and autonomy of things from the beginning (Olsen 2010).

Things have no opposites. They are best defined as assemblages that cannot be broken down into their parts or reduced to their effects (Olsen and Witmore 2015, 191; Witmore 2014, 4). This means that things are neither mere aggregates of their pieces nor bundles of their qualities or properties (cf. Harman 2011, 8–13). Things withhold something of themselves from their relations – there is always an excess that remains untapped by any interaction. There is more to a photograph than efficacy; there is more to a foundation than form; there is more to a wooden barn than material; there is more to a ruined farmhouse than memory. To manifest something of a turf embankment without reducing it to its properties, qualities, actions, or effects is to respect its surplus reality and remain true to its richness of being. Still, one can never gain more than an oblique purchase or indirect access to the legion objects that constitute what has become of a ruined farm on the Langanes peninsula, for they will always exceed any articulation of them. Any understanding of the term, "thing," must begin with an acknowledgement of its radical recomposition outside of any modernist partitioning of the world. This definition of "thing" resonates with the concept of "object" deployed within object-oriented philosophy (Harman 2011) and both terms are far too useful to be thrown out to the scrap pile of abandoned nomenclature. What is

productive about the term "thing" is the gathered reality of an entity; that is, how an internal combustion engine draws together a motley array of other things. What is productive about the word "object" is the *objectum*; that is, an obstruction, that which is exposed, thrown, or cast before anything else.

Still, if all entities are accorded dignity as things from the start, then what makes an object of concern archaeological? Widely accepted among practitioners and the public are objects experienced from the angle of absence – a rusted iron spearpoint without its shaft, a ruined farmhouse without its roof, a section of wall without its extensions, an abandoned village without its inhabitants (see Lucas 2012, 178–184). Though framed from the angle of lack, these things lack nothing in their integrity or being, for if a concrete bastion is not derivative of the engineering outfit that built it during WWII, then once released to its own trajectories it persists on, outlasting the intentions of its makers, offering its rock-solid qualities and dark recesses as a foundation and basement for a house in Kirkenes (Fig. 2). What makes an object archaeological is not what it is, for things exceed their pasts, but how it is deployed toward a telos that is implied by the etymological root, *archaios*, a quality or attribute of the erstwhile or bygone, and of memory or pastness (Witmore 2017b; also see discussion in Nativ 2018).

Again, archaeologists are obliged to resist appropriating things over to neat stories of the past, or rendering them as detached from their present situation. Such an obligation demands a constant struggle for ways to speak of things, to articulate things, without subsuming them to interpretive burdens they are unfit to carry (Olsen 2010). An ethics encompassing all things demands an attitude of care combined with a sense of fidelity (Olsen et al. 2012). An attitude of care implies an appreciation for an entity's well-being and a respect for it in its own being (Olsen 2012). A sense of fidelity suggests a faithfulness to the propensities of things, which demands a different species of theory, one that cannot be applied in the abstract, one that is not forced onto a situation, or which buries the differences made by a given entity under the excesses of its own weighty dictums. Such an ethics implies a generous disposition with respect to the independence and otherness of an abandoned herring factory in Iceland without discursively packaging it with a contrived intimacy for a community of interest (Pétursdóttir 2012). Care for

Symmetrical Archaeology, Fig. 2 House-bunker in Kirkenes, 2016

things in themselves may even demand letting them be, without that obligatory recourse to the *for us* (ibid.).

Approaching things involves feral work. In beginning with things, one cannot be afraid to venture wherever one is led. One has to dare to remain open to suggestions, to being nudged along by idiosyncratic hints while trusting that a solution will emerge. Approaching things is less about being confident, that is, carrying on with the attitude that we have everything at our disposal to confront any situation (Stengers 2011). It is more about having trust, keeping faith that a possibility will reveal itself. In approaching the cape at Svaerholt, it matters whether one aims to undertake an ecological study of the falling population of kittiwakes or to investigate archaeological remains associated with WWII, for suggestions occur within a zone, and a zone disposes one to be attuned to some objects, but not others (compare Lingis 1998). Over the iterative course of a project, brick piers, wooden beams, or rotten floors, soil-encrusted tools, discarded bottles, or tattered bits of fabric suggest aspects of themselves to archaeologists with training and accumulated experience, who carry the expectation of production toward archives, collections, and the fine edge that is a book or article, among other things.

Because the stonewalls of erstwhile barrack blocks are placed under the burden of archaeological relevance, one has to strive to understand their peculiarities, even aside from that which is apparent. Habit, routine, and procedure can make one inattentive to the ambiguities and ineffable qualities of things rendered as background noise. Requisite is an openness tempered by a deep patience, granted the propensity of things to present aspects of themselves apart from what is given over in experience. Becoming attuned to some objects may open the floodgates to other things formerly unobtrusively fused together within the background of immediate awareness. Requisite is repeated research under different weather conditions combined with a cultivated familiarity shaped through accumulated experience including an understanding of the subsurface within different zones, or spaces of disposition. Requisite is creative saturation through other modes of engagement, including photography or video diaries. Still, we will only ever gain some oblique sense of that surplus reality that resists translation. Archaeological practice raises its own problems, which, to repeat, must always be put at risk in light of the situation at hand.

If things are irreducible to other things, if they are more than a standing reserve, then they cannot be replaced by substitutions (Olsen 2010, 2012). If things hold a surplus reality, which can never be exhausted by their interactions, glossed as fetishes, distorted as intermediaries, or limited to the role of mediators, then one must seek to render them in terms of their own idiosyncratic being. One way forward is to focus on their positive differences (Olsen 2010, 156). The positive difference that a wooden fishing boat makes in stormy sea means that it cannot be replaced by a dingy, a life ring, or flippers. The positive difference that precisely joined basalt slabs raised upon four distinct foundation layers makes for Roman traffic means that the Via Appia is patient of supporting a Mercedes-Benz M-class SUV in the twenty-first century (Fig. 3). Such positive differences serve to remind one of the sheer specificity of things and how they exceed any attempts to paraphrase them (Harman 2016, 3).

Again, symmetrical archaeology does not aim to provide a generic body of theory applicable in every situation. Such work runs the risk of succumbing to synthetic routine. Such work limits one to a consistent formula, so that looking for evidence of authority begins to make Chaco Canyon sound like Chavin de Huantar. Rather, symmetrical archaeology offers a series of propositions – symmetry, irreduction, suggestions, and positive differences – to aid in being as subtle as the case at hand; to remain true to the utter peculiarities of each absolutely unique situation. With these aids, it is left to archaeologists to dare to think carefully through what they confront; to remain open to relinquishing an interpretation, what has often been black-boxed as abstracted theory (a tendency among many processualist and post-processualist archaeologists); to trust in the polygonal wall turned Byzantine bastion, the former bathhouse turned garbage pit, or the

Symmetrical Archaeology, Fig. 3 The Via Appia Antiqua, 2010

shattered concrete bunker to lead us on. There are other paths to archaeological knowledge besides prepackaged ideas to be applied in every situation. Symmetrical archaeology provides a benchmark, a common ground from which to root out differences in order to open archaeology to the articulation of diverse pasts.

Pasts Otherwise

Legion are those things which object to a modern historicism where the past is held to be completed, circumscribed within the boundaries of its own delimitation and, thereby, detached from the present (see entry, *Chronopolitics and Archaeology*, for a detailed discussion of this form of historicism). Whereas the Atlantic Wall bastion of Svaerholt was abandoned in the late fall of 1944, shattered concrete casemates, encompassing stonewalls, cannon platforms, roads, turf embankments, and barbed-wire obstacles nonetheless linger on (Grabowski et al. 2014). Here, coextensive in the present, a compulsory past stands still, driven by the tenacious propensities of concrete platforms, broken porcelain plates, or melted glass bottles to persist. Against such an obstinate background, change may be witnessed through the juxtaposition of that which gathers and disperses. Over portions of the Svaerholt headland, a wreckage of plastic fish boxes, footballs, Christmas trees, and floats — all wind-blown debris supplied by drift matter (Pétursdóttir 2018) — accumulates in low lying areas to be buried by grass and heather, bestowing upon the present an increasing diversity of pasts, erratic, fragmentary, and unruly though they are. A symmetrical archaeology recognizes these pasts to be neither successive nor ordered within a series of replacements, but as simultaneous, as coincidental among the legion things that hold something of what was and the myriad relations that seek to release such memories.

Though uninterrupted progress and unrelenting advancement seem to occur along a linear and supercessive trajectory, neither the march of technology nor the unremitting pace of development manifests a definitive break with the past. Even as motors were placed in every conceivable tool, from dentist drills to battery-operated hedge trimers, they continued to be used next to hammers and handsaws. Even though the Allied bombing of Germany ceased in 1945, Frankfurt officials had to still evacuate 70,000 inhabitants due to

the enduring presence of British bombs in 2017. Even though the Western Roman Empire collapsed over the course of the fifth century – throughout the eternal city, and beyond – architectures of the Flavians, Trajan, and Diocletian continue to assert themselves in the present, pressing into the future, far beyond the desires of designers, affecting others irrespective of the aspirations of long-dead Romans. This latency is not only a matter of material, but also of form. Hellenistic roads buried under two meters of accumulation, nevertheless, persevere at the surface in the orientation and dimensions of streets in the Greek city of Argos. Such examples speak more to the topological pleating, folding, and enmeshment of disparate pasts, which gives rise to a sense of time less akin to linear flow than to weather-like percolation (Witmore 2006).

The weight of history, which holds a monopoly on how the past is conceived, burdens things with the expectation that they speak to lived events sealed off in another period. Such expectations are partially tied to the overdramatized relationship (often seen as a conflict) between texts and nontextual material objects. It is indeed the case that the past is shaped through writing about events, and objects that remain, or what becomes of them. But pasts are also produced apart from language or texts: in how the ruination of a building occurs through interactions with rain, microbes, or tree roots; in how we, whether archaeologists or agrarians, recognize change in that which is unfamiliar, in architectures out of place, in confronting strange and alien ceramic forms that are no longer in use, or in grasping a figurine dredged up from dark depths of the soil. Yet to focus on things present should not be confused with presentism (Bangstad 2017), for hammers, handsaws, blockbuster bombs, Trajan's column, or buried road surfaces possess a capacity for manifesting their own peculiar pastness, which may be profitably understood as a species of memory (Olivier 2011). However prevalent may be the conflation of the term with a conscious and wanton act of recollection, this form of memory can cannot be called voluntary. Rather, the inscription of object memories arises amidst adventures with other objects – nails, numerous oak boards, RAF Landcaster heavy bombers, chisels, or oxen-pulled stonerollers. Though expository, such memories may or may not offer suggestions as to the identity of other objects that gave rise to them. We could treat calcium carbonate-encrusted, *opus-incertum* arches – what has become of the Hadrianic aqueduct – as a blank canvas upon which to convey meanings or expressions related to "the slave economies of the classical world" (Barrett 2016, 1685), but remnants standing on the slopes of Ntourmiza or Megalovouni suggest nothing as to whom belonged the hands that set the stones – slave, free mason, soldier, or engineer. Still, what we lose from the angle of history, we gain in another form of memory – in the grade of an *opus signinum*-lined channel, in cutmarks left at the top of a limestone precipice, in the form of stones set within mortar. The memories held within and between things belong to them and are involuntary artifacts of their own past.

It is the tenacity of stone circles that do not shift in the wind, the persistence of Egyptian cosmetic palettes that do not rot, the obstinacy of millennium-old iron tools in Sogndal soils that allows change to be glimpsed through their comparative presence. In grappling with change, archaeology has long struggled with issues of synchronicity or diachronicity (Lucas 2015), terms familiar to history (terms which continue to drive the field of Mediterranean archaeological survey, for example), but understanding change demands a sense of *polychronicity*. This involves a motley array of objects and relations that endure on, that possess within themselves different continua. While subsequent Samothracian generations continue to live amidst a diversity of pasts – what becomes of medieval stone houses, disused water channels, relic terraces, or erstwhile ancient enclosures – they also enact millennia-old rapports, working soil, planting crops in plots delimited by channels, and maintaining water conduits.

Long have archaeologists conceived of change in terms of dynamic processes, where what becomes of the past is regarded as the outcome of a protracted course of entropy and accumulation. Widely understood in terms of formational

processes (Schiffer 1987), according to these precepts actual entities encountered in the present are the result of continual shaping and transformation – corrosion and compaction, decomposition and deposition, erosion and aeolian accretion. Whereas this conception situates ruined aqueducts, buried foundations, erstwhile surfaces, or the accumulated fills above them, as derivative of processes, symmetrical archaeology takes a different stance on the evolution of these old things. For any perspective on dynamism can only occur against backdrop of stability. There are several more points to be made with respect to change.

First, ruins, walls, buried surfaces, or fills do not exist because they change – they change because they exist (Harman 2016, 7). Organic remains, bacteria, and rubble walls are things rather than processes (Witmore 2014); and things change depending on their interactions with other things. If a thick layer of clay is deposited over rubbish-filled ditch, sealing it below the water table, then bacteria will no longer find a hospitable milieu in which to enjoy their wood fodder. Second, formational processes suggest a gradualist image of change. Whether over the long or short term, it is implied that every instant should be accorded equal interest. Yet, not all instances are the same. Some changes are of more consequence for the emergence of what is left of the past than others. With the deposition of a thick layer of clay, an anaerobic bubble emerges to redefine how wood tablets persist in absence of nitrogen-fixing bacteria, as is the case at the Roman fort of Vindolanda. As such, change is often more sporadic and the transformations that occur over the life of a thing is saltational. Finally, the past that was does not exist as an authentic and privileged bedrock situated in a resultant, causal relation to what is present; rather, the things present are what make the past, including processes, possible. Understanding how things give rise to pasts demands a different understanding of causation. Here, *emergent* causation takes over from that which was considered *resultant* (Witmore 2017a). Emergence specifies how objects, whether a Roman auxiliary fort on the Stanegate, the Vindolanda tablets, or the prefect Flavius Cerialis, exceed the components that gave rise to them, and once formed they retroactively define their ingredients as well as their own morphogenetic history (see DeLanda 2006). After organic objects are fully consumed by bacteria, new soils emerge to enter into their own chthonic adventures with hobnails, ceramic jugs, or relic walls (Nativ 2018). No longer derivative of intentional humans, historical processes, or heterogeneous entanglements, wood tablets, buried walls, or accumulated soils now share the stage as generative components in the articulation of pasts.

Criticisms and Clarifications

The foregoing narrative has already highlighted a number of common criticisms and wonton misreadings as points of contrast and prompts for clarification. What follows expands on routine critiques of symmetrical archaeology. Beginning with questions of agency, meaning, and intentionality and moving on to charges of progressive subjectification, this final section works through several critical examples, indicating points of deliberate misreading, and offers further clarifications.

If oak trees, goats, ox-pulled plows, flash floods laden with debris, or backhoes make a difference in the formation of the archaeological record, then it is because they root, inhabit, and furrow; they scour, deposit, and excavate. All these things possess, among other attributes, the capacity for activity; that is, the capacity to modify another object's course of action (Latour 2005, 71). Against such a motley roster of agencies, rash accusations of animism are commonly made. For such critics (e.g., Lindstrøm 2015), symmetrical archaeology succumbs to the same wayward tendencies that possessed those bereaved sons who prosecuted the statue of Theagenes for the murder of their father; the same irrational behavior displayed by the Thasians who, following Draconic law, found the statue guilty and banished it to the bottom of the sea; the same pagan sentiments as the oracle-informed Delphic priests who attributed land barren of fruit to the statue's exile or those who, after it was fished out of the sea, returned the statue to its place and

sacrificed to it as a god (Pausanias 6.11.6–8). Instead, these critics hold object agency to be just another species of projection by an ontologically privileged entity onto inert matter, which lacks one ounce of autonomy (Lindstrøm 2015).

In analogous fashion, others have taken issue with a supposed debasement of intentionality and meaning with a so-called turn away from people. In absence of intentionality, the guilty, we are warned, cannot be held accountable (Van Dyke 2015, 20). By evading the problem of free will, symmetrical archaeology, we are advised, misses how some "non-humans can *originate* action and some cannot" (Graves-Brown 2013, 184). Both critiques conflate symmetry, which is an analytical proposition, with an ethical and axiological declaration of equivalence – no need to rehash early examples that went to lengths to forestall this confusion (Witmore 2007, 547; also see Olsen and Witmore 2015, 192–194). Such cynical reasoning, moreover, abstracts from the specificities of archaeological objects and practices. In archaeology, the explanation cannot be laid out in advance, yet this is precisely what those who campaign for intentionality and free will seek to do. We are left to take recourse in a billiard-ball realism where action is initiated by an esteemed agent to be merely transferred down the causal chain among objects that lack any ability to inflict autonomous blows to each other. This species of reductionism fails to account for concrete bunkers that outlive their makers; for well-built walls of a bygone polis that underpin an eighteenth-century library in Ermioni, Greece; for water conduits that are released to their own trajectories, that form new alliances and offer up unpredicted qualities. Whatever differences these things make cannot be explained by reducing everything to a supposedly primary rapport with a favored interlocutor, thus sidelining bunkers, 2400-year-old trapezoidal walls, or water conduits as merely derivative.

"We cannot escape," others contend, "talking about meanings be they the meanings of past actors, present interpreters, cultural practices, evolutionary trajectories, actants, or assemblages" (Preucel 2016). It is, of course, the case that the world is saturated with meaning, most of which, as archaeology has long recognized, is unvoiced – the precise joints within a stretch of polygonal masonry, the placement of a window in a lookout tower facing an erstwhile harbor, ruins of gate in the saddle of a ridge. Reasserting the importance of such a "pragmatic archaeology," Robert Preucel contends "that a truly 'symmetrical' approach should not oppose people and things, but rather consider how humans combine the material (artifacts) and immaterial (words) in cultural performances to achieve specific semiotic effects" (ibid.). By now, it should be clear that, for a symmetrical archaeology, the relationship between human and world cannot be emphasized at the expense of others. Just as it would be absurd to remove the human element from archaeology, it would be absurd to claim there is no more to portions of polygonal walls, towers, or former gates than their semiotic effects. Preucel's pragmatic archaeology remains fixated on humans as its central concern and, in so doing, it conflates human as observer with human as ingredient and denies things that surplus reality that exists beyond human observation. While "meaning-making practices in the present" or considerations of cultural performances with semiotic effects do not exist free of a human observer, the material pasts shaped out of former timber buildings by nitrogen-fixing bacteria, as we must suppose, do. Myriad are the archaeological objects that exist without humans as necessary ingredients in their emergence. Pervasive are those *non-discursive* aspects of things that exceed their relations to any human observer.

The reasoning advanced by such critics posits a more genuine, more definitive, and purified reality, but this would provide us with insufficient traction in understanding the differences made to former timber buildings by nitrogen-fixing bacteria, to crystalline minerals in exposed agricultural soils by the sun, or to an ancient theater-turned-quarry by oak roots (Fig. 4). Furthermore, these quips over issues of agency, intentionality, free-will, and meaning completely miss the larger point. We need a different metaphysics to provide some purchase on our catastrophic times, when greater-than-gargantuan objects exceed the human ability to master them. Relations between permafrost and methane, between CO_2 and

Symmetrical Archaeology, Fig. 4 Oak roots conspire with foundation stones in a theater-turned-quarry, 2018

seawater, between atmosphere and sun require a very different empirical metaphysics than what we find in reductionist schemes that would situate all nonliving objects as pawns in a game played exclusively by sentient beings. Whether or not scholars are willing to concede this schematic legacy is now of less concern than how it is that coal-fired power plants, glaciers, abandoned uranium mines, landslides, hurricanes, or weighty urban infrastructures have refused to comply with their expectations.

Symptomatic of a wider turn to things, symmetrical archaeology has been subsumed to symmetric anthropology's last ditch effort to reclaim Western authority in the wake of its demise (Fowles 2016). "As it became more and more difficult for Western scholars to make authoritative claims about other people," according to Severin Fowles, "anthropologists began to explore the advantages of treating (non-human) objects like (quasi-human) subjects" (ibid., 12). In keeping with his appraisal that the turn to things amounts to a simultaneous turn away from people, Fowles contends that nonhuman objects "have the advantage of being safer" (ibid.). Suffering from an incurable longing for a loquacious anthropological informant, those scholars who apparently have fallen prey to a renewed interest in things have progressively transformed non-human objects into the perfect subject. Like those Thasians who sacrificed to the false-god of Theagenes, no clemency shall be given – their idols have mouths but do not speak; they have eyes but do not see; they have ears but do not hear; they have noses but do not smell; they have hands but do not handle; they have feet but do not walk (Psalms 115, 5–7).

Such critiques can only stand out against the very background which is rendered null and void by symmetrical archaeology. If we eliminate the opposed realms of culture and nature or subject and object, then why appeal to that familiar valorization of one side above the other? For critics to argue for a process of progressive subjectification is to directly violate the principle of symmetry. Such a frivolous critique offers a better view of the colonial attitude Fowles wishes to unmask in the work of others; for in subsuming the turn to things to deeper historical processes, he must ignore the specific arguments, explanations, and motivations put forth by his colleagues, and thereby deny them a voice – "like so many chessmen available for

anyone to play with" (ibid., 16). One might cast this as yet another case of projection by those who believe nonhumans to be nothing and human politics everything. Yet again, archaeological objects are threatened with being trivialized and ignored in critical misrepresentation. Symmetry reminds us never to make this mistake.

Participants, memories, suggestions: on the surface, the terminology of symmetrical archaeology might seem to redistribute formerly human qualities to that which lacked them, and, thereby, reaffirm human narcissism by reconceiving of the world in our own image (Pétursdóttir 2012). Such suspicions can only be bolstered when we encounter descriptions of plants that communicate through roots, retain memory, and distinguish on the basis of "kin" through rhizomes. And yet, the use of such terminology runs the risk of anthropomorphism only if humans are maintained at center. Indeed, it is the case that the choice of concepts within symmetrical archaeology targeted the premise that memory, agency, interpretation were never exclusive to humans themselves; thus, such vocabulary was deployed in making this assertion (e.g., Olsen et al. 2012, 13). Still, when it comes to understanding the idiosyncrasies of things, this terminology actually blurs the positive differences that autonomous entities make, and which all archaeology seeks to manifest. Incessant is the struggle to cultivate vocabularies and modes of expression as delicate as the situation at hand.

Whatever one makes of the novelty of symmetrical archaeology's contributions, it is worth repeating that the adjectival label "symmetrical" was always recognized as provisional (Witmore 2007, 547; Olsen 2012, 223). Once its liberating effects were expended as a qualifier, it was ready to be shed. However, it remains a challenge for archaeology to fully recognize that we begin, not with a detached past, not with bits of ceramic that act as intermediaries to artisans or PoWs, but with what becomes of what was, with things. Symmetrical archaeology is an inheritor of that longstanding archaeological aspiration to dig to what is fundamental as our objects of study, but not at the expense of sorting out what is real and what is not in advance. It aspires not so much to greater certainty as to making positive gains amidst every present uncertainty. Its stories are diverse, from gatherings of different times in the fabric of Greek city-states or Ethiopian landscapes of abandonment to bovine urbanites living within their own cities on the high plains of Texas or material memories present in a PoW camp in Finnmark, Norway. Ultimately, symmetrical archaeology strives for an archaeology that is not subsumed to history, but is held to be of equal scope; that is, an archaeology that stands as both history's complement and alternative.

Symposion

Fiona Hobden
Archaeology, Classics and Egyptology, University of Liverpool, Liverpool, Merseyside, UK

Introduction

Since the 1980s, the "symposion," or drinking party, has been studied intensively as a major socio-political phenomenon in ancient Greece. Its origins probably lie in the fusion of local drinking culture with practices learned from the Near East in areas where trade opened up not just the transfer of goods but practices and ideas. However, as part of an Archaic Greek culture it developed its own distinctive rituals, forms, and functions. To understand its sociological, political, and psychological dimensions we must look at written, archaeological and iconographic material together.

Definition

"Let us drink!" With this opening invitation, the late seventh/early sixth-century BCE poet Alcaeus from the island of Lesbos (fr. 346) encapsulates the essence of the symposion imbedded in the name: to drink (*poteô*) in company (*sun-*, "with"). As the poem continues, further features emerge. With night only a fraction away, a beloved youth is instructed to take down large painted cups. Reminded first that the god Dionysus gave care-banishing wine to mankind, the boy is urged to fill them up to the brim with one measure of water to two of wine, as one cup jostles with another. Alcaeus' commands draw attention to some specific accoutrements and processes – a serving boy, decorated wine cups, and the mixing of wine –, and aim at a carefree, eroticized, exuberant atmosphere. Here, then, is one symposion.

Step forward in time to the early fifth century and travel across the Aegean Sea to mainland Athens, and a red-figure drinking cup attributed to the Painter of the Paris Gigantomachy provides a glimpse of another party in progress. On one exterior scene (Fig. 1), many of the same attributes are visible. The presence of four young men reclining side-by-side, facing one another in pairs creates a communal dimension. Cups hang behind them on the walls, or rest in their hands, or stand silhouetted on a border below (this border perhaps stands for the table or the floor). If the appearance of stylized semi-naked, beardless youths is not enough to convey an erotic tone, then the bent elbow, outstretched arm, and raised cups of the youths to the far left and right certainly do. They are playing kottabos, a toasting game in which each player aimed the dregs of his wine cup at a target (here, two high poles) in order to claim kisses. A penis cup also stands cheekily to attention below. In addition, the scene contains signs of luxury. The symposiasts recline upon sumptuous striped cushions. They are apparently on the floor, but this may be a visual shorthand for the raised

Symposion, Fig. 1 Painter of the Paris Gigantomachy. Kylix: symposion scene. Greek, Attic. C. 480 BC. Terracotta. 1998.8. (© Michael C. Carlos Museum, Emory University. Photo by Bruce M. White, 2005)

couch (*klinê*) upon which two more symposiasts lie on the interior of the cup. The potential extravagance of this furniture is hinted at by the molded legs and decorative arm of a bronze couch in Athens' National Archaeological Museum (X18922), which, although from the second century BCE, accords with representations of *klinai* from Archaic Painted pottery (discussed by Boardman 1990). Depicted on the wall behind our nubile youths, furthermore, are animal-skin cases for the pipes (*aulos*) and a lyre, symbols of musical performance. Alcaeus might focus on the drinking, but his poem constituted a musical contribution to the symposion, most probably sung to the accompaniment of the lyre.

Taken from the written and material record, these two snapshots of the symposion provide a cumulative vision of a male homosocial occasion characterized by communal drinking, (homo)eroticism, music, luxury, and game-play. Add to this the archaeological evidence of the andron – the distinctive "men's room" that appears at civic-religious then domestic sites from the sixth century onwards, which is identifiable by its dimensions, architectural details, and more elaborate decoration – and you also have an event that took place within closed walls. These walls were lined with 7 or 11 couches in a circle. Like the figures spread around the exterior of our red-figure cup (the symposion continues on the reverse), the occupants' attention was automatically turned towards one another, away from outside. This lent the symposion an inclusive and exclusive air. The communality attested in the name symposion and its shared ventures was reinforced via the dynamics of the architectural space in which it took place.

Key Issues and Current Debates

To understand the symposion it is necessary to read different types of evidence in tandem. Each has a distinct focus and purpose: monodic poetry of the type attributed to Alcaeus was sung at the symposion; figured drinking vessels circulated amongst symposiasts at Athens and beyond; and excavated sites provide access to the physical space they inhabited. Together they construct a composite form. Yet, approached individually, each can shed independent light on the phenomenon; and from the divides arise discontinuities and differences. For, as is shown by poems composed not only by Alcaeus of Lesbos but also, moving from the late seventh to fifth centuries, Archilochus of Paros, Tyrtaeus of Sparta, Theognis of Megara, Solon of Athens, Anacreon of Abdera (who sang at the court of the tyrants Polycrates of Samos and Hipparchus of Athens), Xenophanes of Colophon, Ion of Chios, Dionysius Chalcus and Critias of Athens, the symposion was a multifaceted affair. Composed on the spot, introduced by the original poet, or memorized and performed by others, their songs may survive mainly in fragments. None the less, they preserve the conversations of the event. Through poetry symposiasts might express political sentiments, outline moral positions, praise or criticize a companion's conduct, pursue erotic relationships (especially with younger males), offer hymns, and make statements about themselves. Moreover, verses could be uttered in self-promotion, challenge, or defense. The symposion could therefore be a place for consolidating political alignments, educating young members of the community, forming personal social and sexual bonds, and expressing one's identity with regards to the present group and the outside world – and also disrupting or disputing these.

Of course, pushing together all this written evidence, generated orally at different parties in different towns and at different times, minimizes the diversity of opinions and interests between the poets and their audiences. One ongoing task, then, is to understand the particular agendas of sympotic poets, to understand their corpuses as a whole, and also how their verses (however fragmentary they are now) might have been effective at gatherings beyond their original performance occasion. Ceramic drinking vessels can be similarly interrogated. Many are not only decorated with images of drinking parties, like the red-figure cup above, but were in all likelihood used on convivial occasions. We can therefore think about the items themselves, and about the images on them. There is one problem here. Many of the

cups, kraters, jugs, amphorae and hydrias that we encounter now in museums have no recorded findspot (Lewis 2002: 5 estimates 50%), or were excavated in Etruria (Italy), where they may have been used by local elites before being deposited as grave goods. Thus, we need to put the majority of pots back into the Greek andron, but of course we have no direct evidence of who used them, where or when.

There is therefore an unavoidable risk of circularity when approaching the visual evidence: of understanding how the imagery on pots contributed to the symposion's social and psychological dynamics by bringing to bear one's preconceptions of what these might be, based in part on that imagery. For François Lissarrague, close attention to iconographical detail allowed a way through the problem, and demonstrated the role of sympotic imagery in self-exploration and identity construction by the symposiast. His seminal monograph, *The Aesthetics of the Greek Banquet* (1990), set the vessels and their images circulating around the andron in the hands and before the eyes of symposiasts. As drinkers encountered reflections of their own activities, sometimes idealized to fit a generic model, sometimes vulgarized, sometimes undertaken by raucous satyrs or hat-wearing foreigners, they were confronted through association and humor with the pleasures and difficulties of their own drinking practices (see, for example, Sutton 2000; Osborne 2007; Steiner 2007: 231–264). Wine could be a powerful and transformative potion, as reflected in the character of Dionysus, its transgressive, boundary-blurring, and boundary-pushing deity. The images on the pots thus acted as Dionysian mirrors, showing drinkers how they were and how they might be. They thereby echoed the discussion of appropriate modes of drinking and the attendant dangers expressed in sympotic poetry.

However, the imagery on Greek pots extended beyond sympotic themes, to include mythological and "everyday" scenes. In tandem with oral storytelling through poetry, for example the tales of giants and strife that the philosopher-poet Xenophanes (F1) wished to eject from the symposion, painted pots drew symposiasts towards narratives about the (heroic) past and present. Like Tyrtaeus' martial elegy, scenes of Homeric-style fighting might contribute to the creation of shared memory – linking modern-day warriors to their heroic ancestors – or reinforce a martial ethic. Or scenes of men "courting" boys could titillate as much as Anacreon's poetic expressions of his homoerotic desires. Or sexually explicit scenes of men with women might also excite, whether as fantasies or anticipating real-life action; or in the most graphic or violent scenes they may even express gender power hierarchies. (Archilochus' "iambic" poetry similarly subjected women to sexual exposure through verbal abuse). These are only a few examples; the scenes on Athenian figured pottery are multifarious. It is frustrating not to know more about the precise encounter contexts for specific images, and difficult to avoid speculation when proposing the responses of imagined drinkers – even if that is grounded in what we know about Greek society generally, and through other evidence from the symposion. However, contemplating this limited selection already indicates some potential resonances, and highlights the symposion once more as a venue for conversations about self and society.

Occasionally, however, imaginative leaps are not required. Some drinking vessels are preserved in situ in Greek settlements in androne, or close by in rubbish tips or graves. When this does occur, the results are fascinating. By studying the shapes and images and inscriptions on pottery found in the fifth-century Athenian Agora, Steiner (2002) has demonstrated the incorporation of "élite" sympotic elements into the dining practices of democratic officials (see previously Rotroff and Oakley 1992). Also in the Agora, deposits from the well (J 2:4) of a late Archaic house have revealed more about how Athenians drank at home: the shapes used by inhabitants and the iconographic themes they enjoyed are set by Lynch (2011) within the context of wider household activities and the new democracy. And the physical and chronological dispersal of kraters across three Greek cities in Sicily – Megara Hyblaea, Himera, and Silenus – shows a shift in sympotic activity from public to private events during the sixth to fifth centuries. Rabinowitz

(2009) sets this progression against the political tenor of a proportion of sympotic verse, making the symposion a venue for expressing the tensions amongst members of developing communities, between bids for equality and power (On the basis of Doric practice at Sicily, he also argues that Spartan convivial practice of the *syssition*, far from being atypical as is often thought, was an extreme version of the standard symposion). Site-specific analyses of the archaeological evidence afford new glimpses into the practicalities of Greek drinking, and the sympotic experiences of individuals and communities.

The particular focus on the symposion's civic dimension reanimates Schmitt Pantel's (1992) argument that the symposion – and its ceramic ware – belonged within the wider sphere of civic commensality. It also fits with revisionist interpretations of the poetic evidence. Earlier studies of the symposion evaluated political comments in Alcaeus and Theognis as evidence for the symposion as an aristocratic activity of separation and opposition (Murray 1983). Or they divided poetry into two types – "élite" and "middling" – according to whether its singers reveled in or rejected luxury, and correlated this to a divide in political ideology (Kurke 1992). "Élite" symposiasts rejected the dissemination of their culture and power to less wealthy and less worthy citizens; "middling" symposiasts towed a middle line in their ethics and political relationships (Morris 1996). Hammer (2004) has challenged the very basis for this distinction, attributing it to the erroneous imposition of ideological divisions, while Corner (2010) shows that the symposion could act as a microcosm of the polis, linking its socialization processes to the individual within the community as a whole. By this reading, the symposion bridges the (private) household and (public) city.

The ramifications of this new work for understanding the symposion as a socio-political phenomenon need further consideration. On the one hand, the symposion was clearly enjoyed by a wider selection of individuals on a broader range of occasions than the inward-focused, oppositional "aristocratic Männerbund" formerly postulated (Murray 1983). But the relationship between the event articulated through the poetry and pot-paintings and the potential settings for sympotic performances intimated by the archaeological record could be sharpened by closer attention to specific archaeological settings. For example, allowing that standard issues regarding preservation, excavation, and interpretation may influence the picture, the majority of andrones in the Archaic period appear to have been situated in public buildings, especially at religious sanctuaries. Symposia here automatically took place in cultic contexts, presumably amongst specific individuals on particular occasions. How can this setting help us understand individual and group experiences? Hobden (2011) reminds us of the indivisibility of religion from other areas of life in ancient Greece, and, bringing together the poetry and imagery of the symposion, suggests some ways in which a religious dimension might facilitate the communal dynamics. But it would be interesting also to explore the (related) religious-political dimension.

Together, these studies demonstrate the pervasiveness of sympotic culture. Drinking in company is not merely the preserve of disaffected aristocratic élites; it was part of "mainstream" Greek culture. Or at least, there were occasions when non-élite citizens enjoyed communal drinking, and civic occasions when groups might come together in various guises. Given also variations in settings, membership, and activities from town to town and across time, any single event could be quite distinct. The symposion may have been a major cultural phenomenon, but it was also diverse in expression. Furthermore, the poetic and visual evidence point towards an event that was potentially disputatious, disruptive and dangerous as much as a positive affirmation of identity and facilitator of group bonding. One of the greatest pleasures of the symposion is the continuing challenge to unpack that diversity of experience.

Syrian Archaeological Heritage Management: "Dead Cities" and Living Communities

Kari A. Zobler
Department of Anthropology, University of Illinois at Urbana-Champaign, Urbana, IL, USA

Introduction

Heritage management is at the epicenter of community cohesion and identity construction in modern Syria. Founded as an independent nation-state in 1946, after a significant era of Ottoman and French colonization, the Syrian Arab Republic manages millennia of Syrian heritage, from some of the world's oldest continually occupied cities to transforming expressions of intangible culture. Modern Syria is negotiating the dialectic between tradition and innovation, utilizing the legacy of the past to meet the challenges of the future.

Syria's vast archaeological heritage is managed by the Directorate-General of Antiquities and Museums (DGAM) under the auspices of

the Ministry of Culture. The DGAM was founded soon after Syrian independence and serves an integral role in managing the nation's archaeological patrimony and structuring heritage narratives. The national narrative is one of legitimization through antiquity and the assertion of national identity in the postcolonial era. National museum and archaeological site narratives emphasize majority culture over diversity, minimizing difference by highlighting elements of a perceived shared past and striving toward a common future. It is through the medium of archaeological heritage that the past is recontextualized and the process of identity formation negotiated.

Key Issues/Current Debates/Future Directions/Examples

Archaeological Site Excavation and Protection

Syria's cultural patrimony encompasses a rich tapestry of archaeological and historical sites that illustrate the region's ancient and diverse past. These sites represent human settlement and culture in the Near East from the earliest occupations in ancient Mesopotamia to Hellenization and Islam. Many of Syria's archaeological sites have been scientifically excavated through a combination of national efforts and international partnerships with foreign scholars. Excavated artifacts are curated in one of a network of Syrian national museums, where the past is recontextualized in the construction of present identities through regional and national narratives.

Archaeological sites in Syria are protected by strict national laws against looting and destruction. Local branches of the DGAM operate in each of 14 provinces, often from the offices of a national museum. Permanent site guards are required at all archaeological sites under current excavation. All sites are regularly visited by provincial officials of the DGAM to ensure that they are in stable condition, but consistent coverage is difficult with a lack of financial resources.

The rural locations of many sites offer a unique set of conservation challenges. Many of the environmental factors that motivated ancient settlement in these rural regions are equally attractive to modern occupants. Thus, villages are frequently located nearby, if not directly surmounting, ancient settlements. In the ideal scenario, the ubiquity of modern settlement near ancient sites could foster a community of local stewards to protect archaeological heritage and participate in scientific excavation. Presently, it is a continuing challenge to balance modern concerns with the preservation of cultural patrimony.

Syrian law protects archaeological sites from modern cultivation and construction. Archaeological *tells*, or settlement mounds, are the most evident type of site morphology in Syria, which frequently results in legal protection extending solely to the more visible high mound. Lower mounds or ancient outer towns are not as topographically obvious and are thus often hidden or destroyed under modern agricultural cultivation. Irrigation agriculture is most prevalent, as many regions in Syria are in either marginal environmental zones or reside below rainfall requirements for successful dry farming. Agricultural reliance on irrigation in these regions has artificially raised the water table surrounding many archaeological sites that are not themselves under cultivation. Thus, tells may appear intact on the surface, while access to deep archaeological deposits is rendered effectively impossible by water and salinity. The popularity and economic growth of cotton cultivation, which requires considerably more water than other crops, has only accelerated this process. Numerous well-preserved sites remain, though many have not yet been scientifically excavated.

The DGAM has identified "salvage zones" in regions where archaeological sites require special protections. These salvage zones are usually regions where modern developments threaten to destroy or obfuscate ancient sites. The directorate-general issues new excavation permits to foreign expeditions only in "salvage zones," which carry the incentive of official dispensation of half the excavated material to foreign scholars at the end of the scientific mission. In 1968–1973, the Tabqa Dam Project constructed a hydroelectric dam on the Euphrates River, which created Lake Assad.

Prior to completion of the impound lake, a cooperative Syrian and international effort was undertaken in concert with UNESCO to excavate sites that would be flooded (Freedman 1977). As part of this initiative, standing architecture at sites such as Qala'at Jaabr were conserved and reinforced; a brick minaret from the thirteenth-century mosque at Siffin was relocated to Meskene (Bounni 1977; Burns 1992: 204), along with the relocation of a similar minaret from Abu Hureyra (Bounni 1977). Recently, the DGAM designated a salvage zone in the Halebiye-Zalebiye region of eastern Syria in response to the planned construction of a dam and resultant flooding of nearby archaeological sites.

Many famous and historically important sites have undergone extensive conservation efforts. In 1999, the DGAM partnered with the Aga Khan Trust for Culture under the latter's Historic Cities Programme (AGHCP) to conserve and restore a selection of Syria's historic fortresses, including Qala'at Salah ad-Din and the Aleppo and Masyaf Citadels. The AGHCP provided technical assistance with the restorations, which "encompassed the refurbishment of public spaces, the provision of tourism infrastructure and a number of socio-economic programmes" (Aga Khan Development Network 2007). In 2004, the Syrian Ministry of Culture signed a similar agreement with Italy's Ministry of Foreign Affairs to renovate the Damascus Citadel and the National Museum of Damascus.

In addition to national laws protecting Syria's archaeological heritage, six sites in the Syrian Arab Republic are currently protected by UNESCO's Convention Concerning the Protection of the World Cultural and Natural Heritage (1972). These are, in order of acceptance to the World Heritage List, the Old City of Damascus (1979), Bosra (1980), Palmyra (1980), the Old City of Aleppo (1986), Krak des Chevaliers and Qala'at Salah ad-Din (2006), and the Ancient Villages of Northern Syria (2011), more commonly known as the Dead Cities. There are also a dozen other cultural heritage sites submitted to UNESCO's Tentative List for possible future inclusion. The sites that currently reside on the list are some of the most popular and heavily trafficked tourist destinations in Syria.

Syrian National Museums

Syrian national museums preserve and present the archaeological past, recontextualizing Syria's vibrant cultural heritage for a modern audience. The national museums were created as nationalist enterprises during Ottoman rule, expanded and modified for colonial purposes under the French Mandate, and finally adopted by the nascent Syrian Arab Republic as a means of contextualizing and presenting their cultural heritage in a post-colonial era. The two oldest Syrian museums, the National Museum of Damascus and the National Museum of Aleppo, were both formed from collections of independent nationalist societies (the Arab Academy and the Archaeological Society, respectively), before being subsumed under the government-operated *Service des Antiquités* around 1920.

Today, the DGAM maintains national museums in many of Syria's provinces, each of which draws upon the same corpus of archaeological heritage. Although the network of national museums display similar artifacts exemplifying millennia of Syrian settlement, each museum presents a distinct narrative of Syrian national identity (see Zobler 2011). Several of Syria's archaeological sites, including Palmyra and Mari (modern Tell Hariri), contain small site museums showcasing some of the artifacts discovered. These museums allow visitors to examine artifacts recovered during excavation and provide a broader historical context for archaeological sites and regional histories. These site museums are far more specialized in scope in comparison with the more conglomerate national museums.

Tourism and Historic Site Management

Syria's rich archaeological heritage is presented to tourists with a particular focus on a few sites and national museums. At Syria's most famous and heavily trafficked tourist destinations, local and foreign tourists mingle to explore Syria's cultural patrimony. The drastically reduced entry fees for Syrian citizens encourage national patronage of archaeological sites and museums. In addition to extant ruins, there are also related intangible heritage events such as the Festival of le Crac des

Chevaliers and the Valley for Arts and Culture, which was held in Homs in the summer of 2010.

Many of these sites have ongoing excavations and restoration projects, which contribute to the corpus of archaeological data, while opening new tourism opportunities and conserving sites for future visitors. Ongoing research at these sites affords tourists the opportunity to witness excavation and restoration programs in progress, thereby de-abstracting the work of heritage management and highlighting its importance in the responsible stewardship of archaeological resources.

Visitor Flow at Archaeological Heritage Sites

Syrian management of large sites with significant tourist traffic involves a segmented organization of multiple checkpoints at key areas of interest, usually involving separate entrance fees for high-profile monuments. These checkpoints may be used to manage the number of tourists able to enter an area at any one time for conservation purposes. In practice, only a small percentage of a large archaeological complex is visited by a significant number of tourists, usually in direct correlation with tour bus accessibility. Syrian officials have concentrated their management efforts in these popular zones, but are virtually absent in other parts of a large site. Thus, the more persistent visitor can often experience sites virtually in isolation (and without official supervision) by walking beyond the most commonly visited sectors of a site. Syrian officials combat this tourist tendency in remote zones by restricting access to unguarded structures with locked gates, making them only accessible by guided tour.

Even with large numbers of tourists arriving daily at a few select sites, there is minimal effort to direct tourist movement patterns in Syrian site management planning. The paucity of cordoned-off sections (for either safety or site preservation) or directional signs to suggest a route, by which visitors may experience the site, engenders a management strategy significantly reliant on individual responsibility. Syrian site officials frequently adopt a warden-esque approach to site protection from damage, issuing frequent verbal reminders to tourists as to which portions of the site are off-limits. From a conservation and safety standpoint, this often leads to more limited and inconsistent site coverage, particularly when spread over a large surface area, than more integrative methods utilizing barriers and signage in addition to roving guardians.

It is predominantly the responsibility of individual tour guides to ferry their visitors around sites and give them historical context in the absence of signage. Syrian tour guides require an official license to practice in Syria, thus ensuring relative standardization in the quality of information presented. Foreign tour guides are allowed in Syria, but the majority of foreign tour companies usually outsource to local agencies for Syrian guides. Within the framework of the guided tour, tour guides are comparatively free to construct the narrative for visitors and chart their own course through a site.

Heritage Narratives: Scripting the Past

The narratives presented at Syrian archaeological and historical sites are intimately tied to tourist movement and signage. Small or isolated sites are usually connected in tourist routes by local tour companies or hotels, often constructed as day-trips from a major city. Packaged tours for multiple site visitations reveal how heritage narratives structure tourism marketing. For example, a combination of Byzantine sites outside of Hama has been dubbed the "Dead Cities" and is commonly visited in a single excursion. Sites that may draw a particular audience, such as Krak des Chevaliers and the Saint George Monastery are also frequently packaged together.

Tourists are almost completely reliant on either guided tours or their own tour books to understand the composition and history of a site, particularly at smaller attractions. Signage is often minimal, even at many of the largest and most frequently visited sites, which instead rely on optional tour guides to provide a narrative framework. Print media is relatively scarce at many historic sites and national museums (with a few notable exceptions; see Bonatz et al. 1998; Faraj al-Ush et al. 1999; al Moadin et al. 2006) and virtually absent at smaller sites. Thus, modest or remote sites form a part of Syria's heritage that is often underappreciated because there is so little structuring of the

tourist experience. Additionally, the ability of foreign tourists to visit many of the smaller sites is hampered by Syrian tourist visas, which are valid for only short stays. Thus, it is usually only the extremely dedicated traveler, usually one who has visited the country multiple times, who visits these sites.

The appeal of these smaller sites for many tourists is the opportunity to encounter incredibly well-preserved ruins in virtual solitude. For many foreign visitors, this conjures the romance of exploration that was so prevalent in the nineteenth century. Syrian entrepreneurs often capitalize on the Orientalist mythos in the structuring of the tourist experience. Overtly, vendors offer camel rides (terrain permitting) and meals at "traditional" restaurants designed for tourist consumption. In more subtle manifestations, such as the display of T.E. Lawrence's unpaid bill at the Baron Hotel in Aleppo, Syrian heritage tourism is recontextualized as exotic adventure in a grand tradition.

The site of Serjilla represents an exception to the general lack of signage in Syrian site management. The Byzantine Period site includes astonishingly well-preserved ruins of houses, baths, a church, and tombs, and is perhaps the most impressive of the so-called dead cities. Signage is evenly spaced throughout the major buildings in unobtrusive locations, so as not to detract from the experience of encountering the ruined Byzantine settlement. Information is presented in concise, multilingual plaques (in Arabic, English, and French) with accompanying illustrations. The script places the site in broader historical context and offers summaries of important historical and anthropological concepts related to subsistence and environment, trade, and political organization. Text panels offer architectural reconstructions of a few of the structures to aid visitors in imaging how these buildings might have looked and functioned in antiquity. These illustrative reconstructions are an extremely effective method of disseminating the results of archaeological scholarship without physically altering the sites themselves, which is infinitely more costly and open to editorial interpretation.

Souvenirs and Popular Culture

Syria has enjoyed a long history of souvenir production based on its cultural heritage for domestic and international consumption. International souvenirs began with the postcard industry. These images of historic monuments, traditional costume, and Orientalist themes not only disseminated images of the region to a broadening interested public, but also structured expectations of travel in the Near East for future travelers and provided a framework through which existing travelers conceptualized their own experiences. More cynically, postcards also functioned as instruments of propaganda, particularly during the French Mandate. Today, souvenirs marketed to foreign tourists reference traditional Islamic society, particularly Bedouin culture. Commonly sold souvenirs relate to traditional culture or handicrafts, including woven rugs, water pipes, Bedouin jewelry and metalworking, as well as kitschy Assad memorabilia and wards against the Evil Eye.

Souvenirs produced for a domestic audience often highlight local interests. Among these are the scale models of the water wheels of Hama, one of Syria's most popular destinations for domestic travel. The wheels are fashioned into children's toys, fountains and decorative conversation pieces at varying scales. They are sold in tourist stalls and shops as well as the main bus terminal: the epicenter of Syrian middle-class travel. Another popular icon of Syrian heritage is the so-called Mari Lady, from a fountain statue in the Palace of Zimri-Lim at Mari. Reproductions of the enigmatic, mono-browed goddess of ancient Mesopotamia adorn public squares and private home gardens alike.

Souvenirs are sold in official gift shops at popular sites and in the national museums, but the majority are produced and sold by entrepreneurial vendors. Syria's tourist market supports a thriving kitsch industry, as enterprising individuals sell independently produced handicrafts and postcards (often at a discount from the official site stores) and refreshments to ambling tourists. Traditional-style goods, such as textiles and metalworking, are most commonly sold in the tourist sectors of *souqs* (markets), though today, they are

frequently mass-produced outside of Syria instead of handcrafted by traditional artisans.

Vendor entrepreneurship allows a broad community to benefit from tourist revenues. This cottage industry provides a vehicle for individuals to capitalize on their tangible heritage in a way that is nondestructive to sites. However, the majority of sellers reach their customers by motorcycle across large archaeological sites, which is problematic for effective site preservation. The relationship between independent vendors and site officials is tolerant, though site planners might work in concert with vendors to develop a strategy for effectively reaching customers, while protecting the archaeological heritage on which souvenirs are based.

The Future of Syrian Heritage Management

Syrian management of their archaeological heritage encompasses excavation and preservation initiatives, a complex system of national museums, and a burgeoning tourism industry. The DGAM governs the nation's cultural patrimony through a combination of local efforts and international partnerships. Modern communities thrive beside ancient cities, and entrepreneurial tour guides and vendors capitalize on Syria's past, while economically providing for the present.

The discourse of Syrian heritage has, until recently, been framed as a global assertion of unified national identity and as a mechanism for the communication of provincial identities internally, rather than serving as a means for heritage introspection. Perhaps future heritage narratives will address more contemporary sociopolitical conditions, as Syrian identity continues to be negotiated. The nation's archaeological heritage will surely be an important medium through which such conversations take place.

Disciplina de Arqueología. Departamento Disciplinas Básicas y Especialidad. Facultad de Gestión y Preservación del Patrimonio, Colegio Universitario San Gerónimo de La Habana. Universidad de La Habana. Grupo Cubano de Investigaciones del Arte Rupestre, La Habana, Cuba

Basic Biographical Information

Ernesto Tabío Palma was born on September 29, 1911, in the town of Santiago de Las Vegas, Havana; he died in the city of Havana in 1984. His first studies were carried out in a state school in his hometown. After that, he completed his primary education at Colegio La Salle in the neighborhood of Vedado. In 1928, he entered the Institute of Secondary Education in Havana. He was very fond of aeronautics, and that is why, in 1935, he began working at the National Observatory where he became head of the department. In 1939, he was appointed as meteorology teacher in the Naval School and in 1940 as meteorology teacher at the National Academy of Civil Aviation (Graciella Tabío comunicación personal 12 de Sept. 2011). At the end of the 1940s, Palma joined the Grupo Arqueológico Guamá, which also included the renowned researchers René Herrera Fritot, Carlos García Robiou, Fernando Royo Guardia, and Luis Howell Rivero, among others. At that time, Palma worked with René Herrera Fritot in the investigations at La Caleta site in the Dominican Republic, collaborating on the review of everything published on archeology at funerary sites in the Antilles and translating it into Spanish.

Being a member of the Cuban Company of Aviation, he was appointed to organize the meteorological service; he was the chief until 1946.

In the 1950s, Palma was selected as member of the Junta Nacional de Arqueología y Etnología. In 1951, he published the article "Culturas más primitivas de Cuba precolombina" in the *Revista de la Junta Nacional de Arqueología y Etnología*, where he made a critical analysis of the periodization applied at that time for the groups that populated the island. It was not until 1953 that he was promoted to the United Nations International Civil Aviation Organization; in this new post, he moved to Lima, Peru, as regional vice director of the South American office. In 1954 he undertook extensive exploration of the Chillón River Valley, identifying the Huanchok Gorge, and a population site in Tembladeras, with domestic stone and adobe constructions. Other sites explored in this campaign were the Quillcab cemetery and in Collique, the well-known fortress of Pukara at the top of a hill, in which segments of wall faces of considerable dimensions were still preserved. However, the most important investigations were carried out in the area of Playa Grande, near Ancon, on the central coast

Fernández and Calzada, 2012. During his long stay in Peru, Palma participated in excavations and explorations with prestigious Peruvian archaeologists such as Dr. Duccio Bonavia, with whom he built an appreciable friendship; Yataco and Hernández, 2013. Dr. Jorge C. Muelle, director of Archaeology and History of Peru; Dr. Toribio Mejía Xesspe, sub-director of the National Museum of Anthropology and Archaeology; American Louis M. Stumer; and German Hans Horkheimer.

Palma collaborated with the Museo de Antropología de la Universidad Nacional Mayor de San Marcos and the National Museum of Anthropology and Archaeology, both in Lima, as well as with Ica Regional Museum. In 1955, he was appointed as an honorary member of the Anthropological Research Institute of Lima. His stay of almost 8 years in Peru would be decisive and transcendental for his recognition as an archaeologist. In 1960, he returned to Cuba and was soon invited to be part of the Comisión para la fundación de la Academia de Ciencias; from the moment of its creation in 1964, he was appointed director of the Department of Anthropology, a position he held until 1969. Since 1966, he was recognized as a permanent member of the Council of the International Union of Prehistoric and Protohistoric Sciences. In his work *Prehistoria de Cuba* (1966) written in collaboration with Dra. Estrella Rey, taking a Marxist approach, he recapitulated the archaeological research developed in the country, trying to reconstruct the social context of indigenous communities. In the process, he set a milestone that would revolutionize the national scene forever.

In 1971, Palma defended his PhD dissertation in order to opt for the doctoral degree in historical sciences, before the Scientific Council of the Institute of Ethnography "Miklukho-Maklai" of the Academy of Sciences of the Union of Soviet Socialist Republics (USSR), precisely with the results of the excavations in the central coast of Peru. He carried out archaeological excavations in Cuba for more than 30 years. He stood out due to his theoretical contributions to the design and discussion of the periodization schemes of the indigenous communities that populated the Caribbean, as well as in the choice of a Marxist-based theoretical position that opened new paths in Latin American archaeology. His research was recognized by national and foreign archaeologists, mainly by some founders of the Latin American social archaeology, with whom he had important and inflamed controversies of a theoretical nature. His work, *Arqueología Espeleológica de Cuba*, Editorial Academia, 1972, is a compendium of the archaeological work developed in the Cuban caves from the nineteenth century to that date, the work that was carried out by national and foreign specialists and institutions, which were not linked to Cuba's Speleological Society. In *Excavaciones en la costa central del Perú*, Editorial Academia 1976, he recollected the activities that he developed during his stay in Peru, and his criteria in relation to the cultures that populated the area are displayed. In February 1977, the XIV Congress of the Andean Man was held in Lima, where the closing session was dedicated to pay homage to his scientific work; he also received a diploma of honor from San Marcos National University for his scientific work; Yataco and Hernández, 2013. The same year *Prehistoria de la Costa del Perú* appeared, published by Editorial Academia with part of the text of his PhD dissertation to obtain the degree of doctor in historical sciences. In the *Introducción a la arqueología de las Antillas*, Editorial Científico Técnica 1977, Palma dealt with the regional analysis of the results of the research carried out up to that date, with a Marxist approach that distanced him from the proposal presented by Irving Rouse (1961).

Palma was distinguished by his teaching activity in his major field of study in universities and academic centers of Cuba, Peru, and the former USSR, as well as his expertise inside and outside the country. He was distinguished as an honorary member of a dozen scientific associations from France, the United States, Jamaica, Peru, and Cuba. For his important contributions to the development of the social sciences and in particular to archaeology, he was awarded with the Carlos J. Finlay Order, the highest distinction granted by the Cuban State to workers connected with research. Graciella Tabío comunicación

personal 12 de Sept. 2011. He also has extensive work published in a popular science journal for the general public. He died on February 5, 1984, at the age of 72, serving as senior researcher at the Institute of Social Sciences of the Cuban Academy of Sciences.

Tadrart Acacus Rock Art Sites

Marina Gallinaro
Dipartimento di Scienze dell'Antichità, Sapienza Università di Roma, Rome, Italy

Introduction

The Tadrart Acacus is a sandstone massif range located in the southwestern side of Libya, in the core of the Sahara, close to the Algerian border. The area is today a harsh and dry landscape, inhabited by a few Tuareg families, but it has not always been a desert. During the humid climatic fluctuations occurring mainly in the Holocene, the area was greener and suited for animal and human life. Evidence of the ancient occupations is spread all over the massif and the neighboring areas in the form of open-air sites (isolated finds, scatters of artifacts, or megalithic structures) as well as stratified archaeological deposits preserved in rock shelters and caves. It is in these same contexts that one of the richest concentrations of Saharan rock art is hosted. In 1985, the rock art sites of Tadrart Acacus were inserted in the UNESCO list of World Heritage Sites as an example of "a unique or at least exceptional testimony to a cultural tradition or to a civilization which is living or which has disappeared" (Criterion III: http://whc.unesco.org/en/criteria/).

Definition

Rock art sites of Tadrart Acacus represent an outstanding record of ancient human groups who lived in the central Saharan region during the Holocene, from the early hunting-gathering communities to the emergence of the first Pastoral society, to the development of the Garamantian state (Mori 1965; Barich 1987; Muzzolini 1995; Cremaschi and di Lernia 1998; di Lernia 1999; di Lernia and Zampetti 2008; Le Quellec 1998; Liverani 2005; Mori 2013), until the Tuareg occupation (Biagetti and Chalcraft 2012; Biagetti 2014). The subjects and scenes are painted and engraved on cliffs, isolated boulders or the walls of rock shelters and the rare deep caves. They mainly represent animals and humans, both isolated, in groups and performing daily or ritual activities. Set into the wider archaeological and paleoclimatic framework, rock art adds important elements to the reconstruction of the environmental, sociocultural, and ideological dynamics of the past cultures.

Key Issues/Current Debates/Future Directions/Examples

Discovery and Outline of Research

The presence of rock art evidence from the Sahara was first reported by European militaries and travelers crossing the region since the late nineteenth

and the mid-twentieth centuries. Until recent times, the Tadrart Acacus massif was almost unknown to the international community.

In 1894, F. Foureau reported the first notice about the presence of engravings in the area; in 1926, the Abbé Breuil and his collaborators published the site of In Ezzan, located southeast of Ghat, and about two decades later, Paolo Graziosi worked in the southern areas of Selfufet, In Arrechin, and Tachisset (all sites today in the Algerian Tadrart – Graziosi 1942). In 1955, Fabrizio Mori crossed the western cliff edge of the Acacus, discovering the prehistoric paintings and engravings hosted on the walls of rock shelters and caves. Mori's team explored and documented the northern and central area of the massif, focusing on the area of Ti-n-Lalan (1955–1959) and later mainly on the central and southern wadis. Since 1960, for the first time in North Africa, the study of rock art was supported by excavations, a modern multidisciplinary approach, and new methodologies, including radiocarbon dating (Mori 1965).

In the 1990s, the research in the area was characterized by a new territorial scale, aimed at enhancing the knowledge of the paleoenvironmental and sociocultural dynamics occurring in the massif and its surroundings (Cremaschi and di Lernia 1998; Mori 1998). The conservation issue was one of the research topics of this phase. Since the 2000s, the main aims of research are devoted to a landscape approach and to the contextualization and systematic recording of the rock art. Emphasis on the state of preservation led to identify various causes of decay due to natural and anthropic factors (Cremaschi et al. 2005; di Lernia and Zampetti 2008). Huge efforts are directed toward active actions for the preservation and management of the rock art sites and the wider cultural landscape of the Tadrart Acacus, to tackle the changes taking place in Libya (Cremaschi et al. 2005; di Lernia 2006; di Lernia and Gallinaro 2011).

Nature and Location of the Art

The Tadrart Acacus is dissected by a fossil drainage network resulting in wide valleys and deep canyons – relicts of a landscape shaped by the tertiary equatorial climate – where prolonged processes of fluvial and pseudo-karst actions caused the formation of rock shelters and caves. These morphological features, located on terraces at different altitudes along the steep slopes flanking the wadis and canyons, hosted the human groups since the Late Pleistocene (Cremaschi and di Lernia 1998).

Rock art in the area takes the form of both paintings and engravings and occurs on the walls of the rock shelters and in the rare caves, as well as in open-air locations like cliffs or isolated boulders.

More than 700 rock art sites have been recognized in the whole massif as a result of the specific research projects carried out by the Archaeological Mission in the Sahara (the first archaeological mission was carried out in the massif by Fabrizio Mori between 1955 and 1990s (Mori 1965, 1998); the geoarchaeological surveys in the 1990s by Cremaschi and di Lernia (1998); the systematic rock art surveys between 2001 and 2008 by di Lernia, Zampetti, and colleagues (Cremaschi et al. 2005; di Lernia and Zampetti 2008; Zampetti 2008); the Tifinagh rock inscriptions Project in 2009 (Biagetti et al. 2012); the Saharan Waterscapes Project between 2008 and 2010 (di Lernia et al. 2012)) and by independent researchers (e.g., Choppy et al. 2002).

Rock art sites reflect the geomorphological settings of the massif: small shelters and rock walls characterize the northern area, whereas the presence of a more complex fluvial network in the central and southern areas favored the formation of a higher number of wider rock shelters and caves (Fig. 1).

Around 60% of rock art is presently found inside the rock shelters – which are partially protected from sunlight and main weathering factors – mainly located close to the wadi bottom. The cliffs and the isolated boulders host almost exclusively engravings. The artworks occur as isolated subjects, scenes, or, most commonly, palimpsests of overlapping subjects or scenes differing in technique, style, and chronology.

Styles and Chronology

The definition of styles and their chronology represents one of the main traditional topics of the rock art research. In the Central Saharan massifs, including Tadrart Acacus and the nearby Messak Settafet in Libya and the Algerian Tassili N'Ajjer, the debate has been particularly heated, thanks to the richness of the evidence and the intensity of research. The main controversy spreads about the definition of the chronological depth of rock art.

A long chronology proposed by Mori (1965) was opposed by a short one, mainly developed by Muzzolini (1991). Mori identified the earliest rock art as a Late Pleistocene/Early Holocene production, realized by hunter-gatherers, whereas Muzzolini referred all the rock art evidence to the Holocene, starting with the Pastoral Neolithic. Until recently, the arguments were mainly based on the animal portrayed, stylistic and iconographic considerations, and the presence of patina and superimpositions, while few archaeological or environmental data were analytically considered. Even if a precise chronology is still unavailable, the recent archaeological and paleoenvironmental investigations in the area and its surroundings are contributing to better fix the chrono-cultural associations of the rock art, suggesting a development at least along the entire Holocene, since pre-pastoral times (Cremaschi et al. 2008; di Lernia and Gallinaro 2010). The definition of "styles" here proposed takes into account the terminologies used by Lhote (1958) and Mori (1965). The proposed chronology is correlated with the main phases of human occupation archaeologically recognized in the last decade of multidisciplinary research. The "styles" can be summarized as follows (*contra* – both terminology and chronology – Muzzolini 1991; Le Quellec 1998):

Wild Fauna: only engravings representing wild animals, typical of more humid, southern environments. Big mammals like elephants, rhinoceros, giraffes, wild bovids, and rarely felines and reptiles are represented, isolated, or in groups. These subjects are often represented almost natural size and occur on cliffs and rock shelters located at the wadi bottom. The sites are widespread in the central wadis of the massifs, with a main concentration along the wadi Rahrmellen. On the basis of superimpositions, the nature and weathering of the rock varnish, the type of subjects, and specific stylistic aspects, these engravings are thought to be the earliest form of Saharan rock art. There are possible cultural associations with Early Acacus hunter-gatherers, archaeologically dated to the beginning of the Holocene, after the hyperarid Pleistocene phase (*ca* IX millennium BCE). A type site of the Wild Fauna style is Ti-n-Ascigh, a rock shelter located along Wadi Senaddar (Fig. 1: green dot), where a wide panel with a complex superimposition of engravings shows subjects referable to different styles, from the Wild Fauna to the *Tifinagh* inscriptions (Mori 1965; Cremaschi et al. 2008).

Round Heads: paintings and some engravings decorating the walls of rock shelters and caves. Anthropomorphic figures with rounded heads are often associated with wild animals, especially Barbary sheep and antelopes. The traits are steady; the figures are generally represented in profile and can be realized with different techniques: a simple contour, in flat color, or polychromy. This "style" is characterized by the presence of hunting scenes and complex scenes of dance and ritual activities, traditionally referred to as sacred and symbolic sphere. The Round Head artworks are spread all over the massif, with major clusters along the middle course of Wadi Teshuinat and the southernmost wadis (Gallinaro 2016). The Late Acacus foragers, performing a delayed use of food and a first taming of the Barbary sheep (di Lernia 2001), radiocarbon dated in the area to around eighth to seventh millennia BCE, represent a possible cultural and chronological frame for this art form. The painted couple of Afozzigiar I (Fig. 2), a rock shelter in the middle course of the eponymous wadi (Fig. 1: yellow dot), is a masterpiece of this style (Mori 1998: 191–192; Gallinaro et al. 2008: 218–220).

Pastoral: paintings and engravings representing the most common type of rock art, with thousands of sites throughout the Sahara. The main subjects refer to domestic cattle and pastoral life. Scenes of daily activities, as well as milking and management of herds, alternating with hunting or ritual scenes, emphasize the complexity of these pastoral groups. The artworks are in naturalistic style in flat color or polychromy; the subjects are reproduced in various attitudes and with many details like body paintings, clothing, and hairstyles.

Tadrart Acacus Rock Art Sites, Fig. 2 Couple in Round Head style painted in Afozzigiar I rock shelter. (Photo © The Archaeological Mission in the Sahara, Sapienza University of Rome)

Pastoral rock art contexts are nearly 50% of the total; they are widespread all over the massif with dense concentrations along the main fluvial systems. Indications from excavations both in the Tadrart Acacus (Mori 1965, 1998; Dunne et al. 2012) and Messak, together with radiocarbon determinations on paint samples (di Lernia and Gallinaro 2010, here references), indicate the fifth millennium BCE as the apex of this art style. On the basis of archaeological data, it is possible that this style lasted from around sixth to mid-third to fourth millennium BCE. Uan Amil cave, along Wadi Teshuinat (Fig. 1: red dot – Mori 1965: 124–131; Gallinaro et al. 2008: 157–163), is one of the most famous rock art sites of Pastoral style (Fig. 3).

Horse/Bitriangular: mostly paintings with some engravings. This style features the bitriangular geometric representation of human figures in flat color and records the appearance of domestic horses. Humans are engaged in different activities: pastoral scenes, domestic activities, and conviviality, often in an oasis context, alternate with hunting/war scenes with flying gallop chariots, or fights were humans wield spear or lance. The artworks are mainly located

Tadrart Acacus Rock Art Sites, Fig. 3 Hairdressing scene in Pastoral style in Uan Amil cave. (Photo © The Archaeological Mission in the Sahara, Sapienza University of Rome)

on the walls of rock shelters and are widespread over the whole massif, with major clustering along the central and southern wadis, especially along the course of Wadi Senaddar. The represented scenes reflect the final phases of the Pastoral period and the early Garamantian culture, approximately between the mid-third millennium BCE to first millennium BCE. The chariot of T-Afozzigiar-t site (Fig. 4), along the eponymous wadi (Fig. 1: pink dot), is a good example of this style (Mori 1998: 219; Gallinaro et al. 2008: 210–211). The earliest occurrence of Libyco-Berber inscriptions has been dated to this phase, as first testimony of writing (e.g., Liverani 2005). Those texts carved or painted on the stone walls of the Tadrart Acacus are hardly datable with precision: they cover a long chronological span, ranging from Garamantian to present times and to present day, as "Tifinagh" alphabet is still used by local Tuareg groups (Biagetti et al. 2012, here references).

Camel: widespread style, featured by the representation of camel (*Camelus dromedarius*). Bitriangular highly stylized, human figures, flocks of goats, caravans, palm trees, and hunting or battle scene, painted or engraved, are the typical subjects represented. The high schematism and the low accuracy of the representations and its late date determined a scarce interest by the scholars. The phase is traditionally associated with the classic and final phases of Garamantian culture (third century BCE to sixth century CE), but a more appropriate study of the evidence can open new scenarios about the most recent phases of the massif's occupation. Ti-n-Abrukin site, along Wadi Teshuinat (Fig. 1: blue dot), shows a heterogeneous set of paintings in different styles, where Camel artworks are well represented (Fig. 5 – Gallinaro et al. 2008: 170–174).

Recently the definition of a new "style," labeled as *Modern Camel*, has been proposed to include the highly schematic drawings, both painted and incised, among which are subjects referable to the modern age, like four-wheel drive cars (Gallinaro 2013: 361–362). This evidence is significant both for its heritage value and for the archaeological potential in opening new scenarios about the most recent phases of the massif's occupation (di Lernia Gallinaro 2010; di Lernia et al. 2013). A notable occurrence of four-wheel drive cars (Fig. 6) has been recorded in open-air sites or in rock shelters along Wadi Raharmellen (Fig. 1: orange dot).

Threats to the Rock Art

The rock art is by its nature one of the most fragile aspects of the cultural heritage. It is affected by natural and anthropic threats that can continuously damage it, and the Tadrart Acacus rock art

Tadrart Acacus Rock Art Sites, Fig. 4 Chariot in Bitriangular/Horse style, painted in T-Afozzigiar-t rock shelter. (Photo © The Archaeological Mission in the Sahara, Sapienza University of Rome)

Tadrart Acacus Rock Art Sites, Fig. 6 Four-wheel drive car, Modern Camel style, engraved on a rock shelter in Wadi Rahrmellen. (Photo © The Archaeological Mission in the Sahara, Sapienza University of Rome)

sites are not an exception. Natural factors, like erosional and chemical processes, determined, according to recent estimates (Cremaschi et al. 2008), the vanishing of nearly 50% of the artworks. High risks have been represented by the uncontrolled access to the sites by thousands of tourists and even scholars, washing, scraping, and touching the art, therefore accelerating the natural process of vanishing. Vandalism has been recorded as well. Several actions to reduce these threats have been proposed and partially realized, but the major project to create a national park has never been implemented (di Lernia and Gallinaro 2011, here references). The isolation of the region, after the 2011 uprising in Libya, represents a new and uncontrolled threat to the heritage. In 2016, due to the continuous political instability in Libya, the UNESCO inscribed all the Libyan sites on the List of World Heritage in Danger (https://whc.unesco.org/en/news/1523/).

Future Directions

The region is currently inaccessible, and the future of the rock art is highly problematic. The immediate actions have to be directed to the preservation, monitoring, and dissemination of this fragile heritage that needs a broader involvement of the local authorities and communities. Short- and medium-term actions need to be addressed to improve the available documentation, implementing and expanding digital online repositories. This would have a twofold result, both on the preservation and managements issues and on the archaeological and anthropological research. On the side of rock art research, the systematic analysis of the artworks will allow an in-depth analysis of the sites, favoring a contextual approach and a broader analysis of local dynamics within the Saharan framework.

Taiwan: Archaeological Museums

Michael Ryan
Independent Scholar, Dublin, Ireland

Brief Definition of the Topic

Taiwan has a vibrant museums sector which has seen recent capital developments of older museums and the creation of new ones, both site and regional museums, with strong archaeological and ethnographical departments and exhibitions. At the top of the hierarchy are the national museums in Taipei of which the National Palace Museum (NPM) (National Palace Museum n.d.) is the largest, most visited, and internationally best known. This museum has at its core the very substantial collection of antiquities and works of art from the Palace Museum in the Forbidden City in Beijing. The Palace became a museum in 1925 on the departure of the Puyi Emperor. Much of the collection was taken away by the Kuomintang authorities from 1931 for safekeeping in the face of the Japanese invasion and moved about China for two decades before approximately a quarter of the collections still in their control were taken to Taiwan during the evacuation of the mainland by forces and people loyal to Chiang Kai-shek. This marked the end of the Chinese Civil War and the establishment of the Peoples' Republic on the mainland. The collection includes a great range of objects derived from archaeological sites and casual discoveries to works of art and craft created for the Imperial Court or collected by the Imperial families throughout the centuries. The NPM houses, in recently renovated and extended galleries, extensive exhibitions illustrative of the history and archaeology of China with a strong emphasis on prestige objects of high aesthetic value. The guiding principles are art historical and culture historical. The museum has a strong presence in scholarship, and its activities are supported by a research library which contains many manuscripts and early Chinese printed books of importance, laboratories, and restoration and conservation facilities. The PRC maintains a continuing claim to the island as part of its territory and to the collections in the NPM.

The collections in the possession of the Institute of History and Philology of Academia Sinica in Taipei are of the highest archaeological importance and derive from fieldwork carried out in China under the auspices of the Academy (founded 1928) (Museum of the Institute of History and Philology n.d.). Members of the Academy, who moved to Taiwan following the Chinese Civil War, established the institution in Taipei where, after an initial period of difficulty, it began to flourish with the expansion of the economy. The Academy maintains a strong interest in

Chinese archaeology and ethnology, and its collections reflect recent fieldwork as well as the inheritance from the institution's past.

The National History Museum, Taipei, founded in 1955 has at its core material brought from mainland China principally from Henan Museum and includes substantial amounts of archaeological material. Its wide remit covers history, art history, and decorative arts. It maintains strong links with museums in the PRC (National History Museum n.d.).

The National Taiwan Museum in Taipei, housed in a colonial Japanese building, has important ethnographical collections illustrating the material culture of the indigenous peoples of the island and has the earliest human remains from Taiwan dating to about 12,000 BCE. The scope of this museum encompasses natural history as well as ethnography (http://formosa.ntm.gov.tw/web/en/exhibition.aspx).

The National Museum of Taiwan History in Tainan City opened in 2011 explores the history and archaeology of Taiwan from the Paleolithic to the present day. It has a strong interest in folklife studies (National Museum of Taiwan History n.d.).

Important museums built to display the results of excavations include the Shihsanhang Museum (Shihsanhang Museum n.d.) and the National Prehistory Museum incorporating the results of excavations at Peinan, Tainan City (National Prehistory Museum n.d.). The museum is part of a wider heritage complex which includes a museum of human rights recalling the oppression of the early days of the Kuomintang government of the island (Explore Taiwan's first museum of archaeology n.d.).

Tamaki Makau-Rau Accord on the Display of Human Remains and Sacred Objects (2005)

Cressida Fforde
National Centre for Indigenous Studies,
The Australian National University, Canberra, ACT, Australia

Introduction

The Tamaki Makau-Rau Accord on the Display of Human Remains and Sacred Objects was adopted by the World Archaeological Congress (WAC) in 2006. Drafted by indigenous and non-indigenous people with expertise including cultural heritage, museums, and archaeology, the Accord provides six key principles for decision making around the display of human remains and sacred objects. Developed and proposed in November 2005 at a WAC Inter-Congress held in Auckland on the "Uses and Abuses of Archaeology for Indigenous People," and adopted in January 2006 by the WAC Council, the Accord supplements two other WAC ethical codes that are also relevant to archaeology, museums, and the study of

indigenous human remains and cultural heritage: *The Vermillion Accord* (1989) and *The Code of Ethics of Members Obligations to Indigenous Peoples* (1990). It should therefore be seen as an additional example of development, by indigenous people and archaeologists, of guidelines to ensure consultative and collaborative ethical practice, although focused on display and exhibition rather than current and future research. In its preamble (see below), the Accord stipulates that its definition of "display" includes conference presentation or publications, and thus incorporates display of *images* of human remains and sacred objects as well as the human remains and sacred objects themselves.

Definition

The Tamaki Makau-Rau Accord consists of a preamble and a set of six principles:

> In recognition of the principles adopted by the Vermillion Accord, the display of human remains and sacred objects is recognized as a sensitive issue. Human remains include any organic remains and associated material. Sacred objects are those that are of special significance to a community. Display means the presentation in any media or form of human remains and sacred objects, whether on a single occasion or on an ongoing basis, including conference presentations or publications. Community may include, but is not limited to, ethnic, racial, religious, traditional, or Indigenous groups of people.
>
> WAC reiterates its commitment to scientific principles governing the study of the human past. We agree that the display of human remains or sacred objects may serve to illuminate our common humanity. As archaeologists, we believe that good science is guided by ethical principles and that our work must involve consultation and collaboration with communities. The members of the WAC council agree to assist with making contacts within the affected communities.
>
> Any person(s) or organization considering displaying such material or already doing so should take account of the following principles:
>
> 1. Permission should be obtained from the affected community or communities.
> 2. Should permission be refused that decision is final and should be respected.
> 3. Should permission be granted, any conditions to which that permission is subject should be complied with in full.
> 4. All display should be culturally appropriate.
> 5. Permission can be withdrawn or amended at any stage and such decisions should be respected.
> 6. Regular consultation with the affected community should ensure that the display remains culturally appropriate.

Key Issues

Many museums and other collecting institutions around the world hold human remains. With the rise of the reburial movement in the 1980s, there has been considerable debate about the repatriation of remains whose location in museums without the consent of source communities has been strongly contested by indigenous groups worldwide, but particularly from Australia, New Zealand, Scandinavia, and North America. The reburial movement has led to significant changes in museum policy in these countries and some others, particularly the UK (Simpson 2002; Fforde and Hubert 2006; Turnbull and Pickering 2010; Pickering 2011). Deep concern about the display and scientific use of human remains has been voiced by indigenous groups as a component of the reburial movement (Hammil and Cruz 1989; Fforde et al. 2002; Watkins 2002, 2010), with some groups requesting that remains be taken off display as a first step in negotiations for repatriation with the holding institution (Hubert 1989: 131). In Australia, the early 1970s witnessed the first shifts in museum policy, with some institutions resolving to no longer accept newly discovered Aboriginal remains without express permission from the source community, and to remove human remains and significant cultural material from display.

Analysis of the ethics of display and the adoption of new policy and guidelines has been in response to indigenous concerns (as has the development of particular policies – see Museums Australia 2005) and the Tamaki Makau-Rau Accord should be viewed mainly in this context. However, the preamble to the Accord makes it clear that these principles are not aimed at solely indigenous remains and the debate around display has had broader analysis. Indeed, over the past decade there has been increasing discussion

about the use of curated human remains of any geographical origin and the ethics of their display, including under what circumstances and how remains should be exhibited and viewed, particularly by the public (Sayer 2010: 95–109). Points of discussion have included, for example: respect for the wishes of the deceased; whether or not consent was given by kin; concerns and requests voiced by source communities and the public; the educational value of display; and the meaning of scientific and public interest in human remains and burial practices (Alberti et al. 2009; Sayer 2010: 95–109). In the UK, for example, discussion about Gunther van Hagen's Body Worlds (an exhibition of human and animal bodies in a variety of postures which have been preserved through plastination), arguments raised by Pagan groups about the treatment of the ancient British dead, internal and external debate by individual museums, government and professional organizations, and the work of the Human Tissue Authority (a nongovernmental public body in the UK created by the 2004 Human Tissue Act which, broadly, regulates the use of human bodies, organs, and tissue for purposes that include research, transplantation, education, and training), among others, all demonstrate the work conducted in this area (Swain 2002; Alberti et al. 2009; Sayer 2010: 95–109).

Policies and guidelines developed during this period by museums and professional bodies in relation to holdings of human remains frequently include sections relating to display as well as repatriation, although they vary in their advice (e.g., Wellcome Trust n.d.; Museum Ethnographers Group 1994; Department of Culture, Media and Sport 2005; Museums Australia 2005; and see Pickering 2011). While the international debate rarely deals with the display of images of human remains (whether in publication, exhibition, or presentation), those in countries with indigenous populations have addressed these issues. Thus, for example, the display of remains and images of remains (and replicas of them) is considered in section 1.4.10 of *Continuing Cultures, Ongoing Responsibilities: Principles and Guidelines for Australian Museums Working with Aboriginal and Torres Strait Islander Cultural Heritage* adopted by Museums Australia in 2005, which states that human remains:

> should not be displayed in public, except in special circumstances where parts of the remains are an integral part of other items, such as human teeth incorporated in an item of personal attire. In such cases the traditional custodians or those authorised by them, must agree to the display of such items. Equally, images and replicas of ancestral remains held in museums must not be exhibited or in any other way made available to the public without the prior permission of the traditional custodians or those authorised by them. (2005: 18)

Although the reburial debate has frequently focused solely on human remains, this by no means always reflects the viewpoint of those of indigenous source communities (e.g., Maddra 1996; Tapsell 2000). Thus, it is not surprising that the Tamaki Makau-Rau Accord also encompasses sacred objects. Like human remains, sacred objects in museums and other holding institutions have also been the subject of requests for repatriation and/or removal from display, and the formation of ethical guidelines around their display and exhibition is similarly contextualized. In some instances, issues surrounding display of sacred objects predates discussion about repatriation. Thus, restricted ceremonial objects were removed from display by the South Australian Museum certainly in the 1970s and there is some evidence that this had occurred in the 1930s (Clarke and Anderson 1998: 172, 173).

It is also important to note that national legislation and policy in the USA and Australia encompass both human remains and sacred objects. Thus in the USA, *The Native American Graves Protection and Repatriation Act* (1990) relates to human remains and cultural items (including funerary objects, sacred objects, and objects of cultural patrimony). In Australia, sections 1.5.9 and 1.5.10 of *Continuing Cultures, Ongoing Responsibilities* deals with the display of sacred objects as well as images and replicas of them, setting out that such items should not be displayed to the public without the express permission of traditional custodians, and that museums should make visitors aware of the presence of such items (2005: 19).

The Tamaki Makau-Rau Accord therefore reflects deliberation on the issues of display

around human remains and sacred objects that were driven initially by indigenous concerns about the continued curation of their ancestral remains in museum collections, but developed into a broader context internationally. It demonstrates continuing discussion around the ethics of archaeology, particular that of the indigenous past (e.g., Zimmerman et al. 2003; Phillips and Allen 2010). Considered together with the Vermillion Accord and the Code of Ethics on Members Obligations to Indigenous Peoples, the Tamaki Makau-Rau document also reflects the role of the World Archaeological Congress in this debate and the development of the ethics of professional practice in archaeology and related disciplines.

Tamgaly (Kazakhstan), Petroglyphs within the Landscape

Boris Zheleznyakov[1], Samat Sapatayev[2] and Julien Biver[3]
[1]Archaeology, History, A.Kh. Margulan Institute of Archeology, Almaty, Kazakhstan
[2]Department of Archaeology, Social Sciences Institute of Selcuk University, Konya, Turkey
[3]University of Liège, Liège, Belgium

Introduction

The world famous monument of rock art at Tamgaly (also known as Tanbaly in Kazakh) is located in the Zhambyl District of Almaty Region, 170 km from Almaty accessible via an asphalt road that to the northwest that follows the low Chu-Ili mountains stretching from the river Copa in the southeast toward the lake Balkhash. The Tanbaly Reserve Museum was created in 2003 and is responsible for managing the heritage of this archaeological complex. In 2004, Tanbaly was inscribed on the World Heritage List by the UNSECO, which placed the responsibility, mostly on the Republic of Kazakhstan, to preserve and develop the site. The monument is annually visited by thousands of tourists from near and far abroad, despite the distance from the highway and the relatively hard continental climate. A new visitor center is being built which will host a rock art museum (Figs. 1, 2, and 3).

Definition

Tanbaly – one of the most intricate structured petroglyph complexes – differs from many other larger and smaller rock art monuments in that the main part of the petroglyphs in the central part of the gorge is considered to be an open-air sanctuary composed of a layer of Middle Bronze Age petroglyphs made in the "Tanbaly's style" described by A.E. Rogozhinsky. This stratum is mostly noticeable in the central part (stamped on all convenient and noticeable stones). A small number of petroglyphs on the complex, both in Tanbaly and Shoshkaly, can be attributed to an earlier period, some of them attributed to the "Kulzhabasy type" though these are only single images. The petroglyphs in Tanbaly will receive many revisions and adaptations from the Bronze Age to today, which indicates the long evolution of the local tradition, despite significant chronological interruptions in the tradition of pecking.

Key Issues/Current Debates/Future Directions/Examples

The sacredness of the Tanbaly area has been determined by the presence of a unique "open-air exposition" – a synchronous and dense layer of petroglyphs, which has a diverse repertoire of scenes with bright anthropomorphic and zoomorphic figures, made in a single artistic style called "Tanbaly style" or "Tanbaly type petroglyphs." The rock art tradition in Tanbaly belongs to a very ancient art which has connections to neighboring regions in Central Asia and was probably brought by inhabitants of Central Kazakhstan. This is confirmed by the numerous and unique carvings of the later historical periods: the so-called Begazins, as well as Saks, Usuns, Syanbi, Huns, Iranians, ancient Turks, Dzungars, and Kazakhs. These petroglyphs are often among the best examples of their chronological periods in terms of artistic merit and the very uniqueness of images. Many of them find direct analogies in rock art and not only art on wide spaces from Transbaikalia and Mongolia to northeastern Iran

Tamgaly (Kazakhstan), Petroglyphs within the Landscape, Fig. 1 The location of the Tamgaly complex on the map of the Republic of Kazakhstan and Almaty region

Tamgaly (Kazakhstan), Petroglyphs within the Landscape, Fig. 2 Detailed drawing of the plane 118, group IV (6 "sun-beam" and other petroglyphs of the Bronze Age are rendered in black)

Tamgaly (Kazakhstan), Petroglyphs within the Landscape, Fig. 3 "Sunhead" on the bull, a group of petroglyphs III

and Scandinavia. These petroglyphs are evidence that the late permanent and temporary inhabitants of Tanbaly worshiped the area. They worshiped the sacred landscape around the Tanbaly river that exists thanks to two sacred springs in the upper reaches of the gorge. In addition to the unique petroglyphs located directly on the rocks of the Tanbaly Canyon, divided between different 6 groups, there are up to 30 separate locations, subgroups, and subcomplexes in that area. The ancient and medieval history of Tanbaly's area has also been determined using the complete archaeological data consisting of excavations and studies about settlements and burial grounds, altars, and quarries.

Petroglyphs of Tanbaly were carved out using stone or metal tools in the pecking technique. All of them were divided into 48 separate complexes during documentation. The real masterpiece of rock art is considered to be a sizeable plane with an impressive six images of "sun-headed" deities (?), carved over small images of people dancing

and praying. The large size of the early petroglyphs, their unique visual content, and iconography put them on a par with the most valuable images of the rock art of Central Asia. Among the thousands of petroglyphs, Tanbaly stands out the homogeneous series of the most ancient images created at the turn of the thirteenth-fourteenth century BC. This period is related to the development of southeastern Kazakhstan (Semirechye) by the shepherd tribes of the Andronovo. Petroglyphs of the Bronze Age of Tanbaly testify to the highest level of cultural and artistic development in the widespread territory of Central Asia. The specificity of these drawings, as described by A.E. Rogozhinsky, i.e., large sizes from 25 cm up to a meter wide, technology, style, iconography, repertoire, and the presence of a narrative design, helps the visitor to attribute these to the Tanbaly type.

The central plane of Tanbaly is the frieze of the "sun-headed" characters of the Bronze Age: it is composed of six large anthropomorphic figures differing in height (from 52 to 74 cm), showing a "nimbus," with different hand positions (raised or lowered) and facing the left (west) or the right (east) or forward (south or north). Above them is a figure composed of a torso and a head which could be interpreted as a seventh (?) "sun-headed" character. From the bottom left, one can see two opposing figures of people in a prayer pose ("adorants") and above – a fragment of the scene of the "sacred marriage."

The panel contains all the main types of Tanbaly sun-headed characters, depicting a collection of "gods" (?) as well as scenes of ritual worship. This composition has not yet been documented anywhere else.

Eleven anthropomorphic figures can be attributed to the early Iron Age: ten dancing warriors with axes and, in the center, the figure of a woman in labor. Above a horseman, a wild boar, and other animals in the Saka "animal" style can be seen. Some figures overlap the images of "sun-heads," but in general they harmoniously complement the composition of the Bronze Age and convey the Picture of the Universe in the ideas of the ancient nomads. The rest of the petroglyphs were created in the Middle Age and later.

The landscape at Tanbaly is particularly typical for the vast region of Chu-Ili. The most probable reason why the people of the Middle Bronze Age chose Tanbaly for these rock carvings lies in the esthetic qualities of this area. The beautiful landscapes of Tanbaly that are concentrated around Tanbaly's river were canonized by the inhabitants and transformed the area into a cultural region. The images composing the rock art were selected because of the sacred value they held in that period for these populations.

Today, mainly the cultural landscapes are "exploited" in Tanbaly though this exploitation should be extremely careful. The general organization and disposition of tourist routes were created by architects Imanbekova K.I. and Yatsenko Ye.L. who wished to "open this site and make it accessible [. . .], give access to the site while avoiding degradations and provides good management methods of the site.[. . .]".

Situated on Tanbaly's territory can be found seven burial grounds of the Bronze Age (Tanbaly I and II, IV–VII, Karakuduk II), arranged mainly along the main valley, on the right and left banks of the river Tanbaly, whereas Tanbaly I and II and Karakuduk II are located on the foothill plain. All the monuments occupy elevated areas in relief (cones, gentle slopes of the hills) and are covered by an alluvial layer. Tanbaly I, IV, V, and VII burial grounds are relatively small (250–400 m^2) and foster a limited number of graves (15–20). In the largest burial grounds of Tanbaly II, VI and Karakuduk II, a total of 30–50 graves have been found in the area ranging from 500 to 1500 m^2.

Over the years, excavations were carried out on all the mentioned sites, and, although their degree of study varies, the data obtained, including the determination of the absolute age, made it possible to carry out cultural and chronological attribution.

All the burial grounds of the Bronze Age at Tanbaly belong to the Andronovo culture and historical community. These monuments belong to Atasu (Central Kazakhstan) and Semirechye variants of the Andronovo culture. They reflect the migration processes of the population in Southeast Kazakhstan in the Middle Bronze Age.

The most ancient sites of the complex are the burial grounds of Tanbaly I, V, and VI, which were used simultaneously from the second half of the thirteenth to the fourteenth century BC. The particularity of the burials relies on the position of the bodies, lying on their side in large stone boxes. These boxes are buried inside round or square fences formed by vertical stone slabs. Burial inventory is represented by elegant ornamented ceramics and bronze ornaments.

Settlements in Tanbaly are located exclusively in the mountainous part of this region. Settlements occupy a small area of 300–1200 m^2 and are located in different geomorphological conditions: on wide sections of valleys, gentle slopes of small canyons (sai), or on elevated sections of so-called "hanging" valleys. Despite differences in topography, all sites have a south, southwest, or southeast exposure. The presence of remnants of stationary buildings (dwellings, livestock pens) in most of these settlements, as well as their location, indicates their long-term, mainly seasonal (winter), use by ancient pastoral communities in Tanbaly.

Many of the famous settlements of Tanbaly are multilayered containing cultural remains of several historical eras. Excavations were carried out only in two settlements – Tanbaly I and V. The most important stratigraphic data was obtained in the settlement of Tanbaly I, where cultural strata of four historical periods were revealed.

Study History

Among the most famous monuments of rock art, the most striking and significant one is the complex of rock carvings of Tanbaly. Undoubtedly, the discovery of Tanbaly is, to this day, one of the most outstanding achievements of Kazakhstan archaeology. The discovery was made in 1957 by archaeologist A.G. Maximova, who published her research in 1958 in an article illustrated with high-quality photographs taken by A.A. Popov. This article provides chronological periodization and dating of the petroglyphs. It can be considered that the discovery of the Tanbaly petroglyphs became the starting point for the scientific study of rock carvings and gave a new direction to Kazakhstan's archaeology. Years later, A.G. Maximova together with A.N. Maryashev and A.S. Yermolayeva published a joint monograph on this site, thus assembling the results of numerous studies and giving a description of more than 2000 petroglyphs, as well as highlights of the main groups.

The research topic of Tanbaly petroglyphs was developed by the works of A.G. Medoeva – one of the first archaeologists to study petroglyphs in Kazakhstan. Today, one of the main topics of study in Kazakhstan is still the documentation and publication of petroglyphs with attempts to interpret them in their context.

Works by A.G. Medoeva, A.G. Maximova, A.N. Maryashev, and A.S. Yermolayeva attracted the attention of scientists and the general public. As a result, Tanbaly became one of the most famous and iconic cultural heritage sites in Kazakhstan, a center of archaeological tourism for both local and international visitors. The UNESCO project "The Great Silk Road: the way of the dialogue of cultures," international expeditions organized along the Silk Road, seminars, and conferences, and literature on this topic also greatly contributed to Tanbaly's fame. Today, Tanbaly has been included in the UNESCO World Heritage List, and as a result, a museum-reserve has been created on the area.

Ever since 1982, A.N. Maryashev has led extensive archaeological research of the monuments of Tanbaly's gorge and its vicinity. Excavations were carried out on the Bronze Age burial grounds, which accumulated important materials which helped solving the issues related to petroglyphs' chronology and the general historical situation in the Zhetysu region. The description of petroglyphs in Kazakhstan has been published by a French archaeological mission in Central Asia.

From the 1990s to today, research in the Tanbaly gorge has been conducted by the Research Institute of Material Culture Monuments. These works were associated with the study of petroglyphs and their conservation. Considerable work has been carried out on the geomorphology of the gorge, the documentation of drawings, and their chronology; a set of conservation works was also carried out, including the "freezing" of cracks, removal of modern inscriptions, and the pasting of exfoliated pieces of stone.

An extremely important role in the study and preservation of the cultural heritage of Tanbaly was played by the UNESCO-Kazakhstan-Norway international project (2001–2004).

With the discovery of an ancient sanctuary with rock carvings of several epochs in the scientific world, attitudes toward the phenomenon of rock art have changed. In the 1950s and 1960s, archaeologists were still skeptical about petroglyphs being a valuable historical source. Back then, it was still believed that the datation of what seemed to be the oldest petroglyphs of Kazakhstan could not be established. Over time, such ideas have changed. This was primarily preceded by persistent research by archaeologists who worked on the monument over a very long period of time. Today, Tanbaly is well known far beyond the borders of Kazakhstan. The site is an area of interest for experts, archaeologists, art historians, and religious scholars. Tanbaly petroglyphs attract professionals and tourists from around the world as these petroglyphs are considered to be unique.

What contributes to this uniqueness? In recent years, archaeologists have found many new monuments that are not inferior to Tanbaly both in the number of drawings or in their expressiveness. For instance, in the Kulzhabasy mountains, ancient drawings reaching 2 or 3 meters have been discovered covering diverse scenes. In Akainar, the image of a bull with horns reaches almost 4 m long. In the mountains of Eškeolmes, there are more varied scenes: petroglyphs from different eras allow us to trace the evolution of rock art for a long period, including many drawings from the early Iron Age.

Compared to these sites, the Tanbaly petroglyphs compose a bright monument and a sanctuary, which has now become an open-air museum of outstanding global significance. Bright pictures are the creations of unknown, brilliant artists of their time. The image of sun deities, characters dressed in animal skins, images of animals, and hunting scenes – they are all gathered together and easily accessible for all to see. Famous researchers have developed a periodization of drawings, found out when and what tribes populated the gorges of these mountains. But this does not mean that many controversial issues in the study of drawings have already been resolved. Every year, archaeologists find new monuments and clarify the time of the appearance of drawings, the influence of neighboring regions, on the culture, and art of the Zhetysu tribes. The Tanbaly region has become a kind of training ground for the study of rock art. Here is the scientific and educational work. Employees of the museum-reserve explore petroglyphs, preserve and promote them, and show the contribution of the people of Kazakhstan to the treasury of world culture.

Tangible Heritage in Archaeology

Fekri Hassan
Cultural Heritage Management Program, French University in Egypt, Cairo, Egypt

Introduction and Definition

The term tangible heritage refers in general to all the material traces such as archaeological sites, historical monuments, artifacts, and objects that are significant to a community, a nation, or/and humanity. The term is often used to distinguish such heritage elements from "intangible heritage," recognized by UNESCO in 2003, to refer to practices, representations, expressions, knowledge skills, as well as instruments, objects, artifacts, and cultural spaces associated therewith of living communities. The term "intangible heritage" replaced what was referred to in an earlier UNESCO document in 1989 as traditional culture and folklore. The designation of an intangible category of heritage led to the distinction of varieties of "material" archaeological and historical elements of heritage – "tangible heritage."

In the UNESCO 1972 convention, what is now called tangible heritage included monuments, sites, and buildings. This designation goes back to the Venice Charter (1964). Mostly concerned initially with archaeological sites, the term was later broadened to refer to groups of

buildings, vernacular architecture, and industrial and twentieth-century-built heritage.

By 1992, the UNESCO World Heritage List recognized a category referred to as "cultural landscapes," which included places and areas shaped through human activities over numerous generations such as terraced cultivated fields or desert oases, whether inhabited by living communities or abandoned; natural sacred sites of mountains, springs, wells, rivers, and other natural features; historical gardens; and other landscapes designed and maintained intentionally.

Key Issues/Current Debates/Future Directions/Examples

The emergence and popularity of the term "non-tangible" (later intangible) heritage and hence "tangible heritage" was due to an increasing awareness of the role of culture in politics and economics in the 1960s. The growing interest in culture as a means of defining ethnic identities popularized the use of [cultural] heritage to refer to the "cultural background" of a group. Most of the ethnic groups seeking recognition and equity were distinguished mostly by their language, "folklore," and customs, i.e., more by what came to be known as intangible heritage vis-a-vis tangible heritage.

The recognition of intangible heritage within a sociopolitical context in the twentieth century and consequently the emergence of the term "tangible" heritage were defined previously on the basis of distinguished architectural buildings and monuments. Although the [tangible] cultural heritage was broadened to include "sites," the criteria for selecting tangible heritage on the world heritage list are predominantly biased toward architecture, buildings, human settlements, land use, technology, monumental arts, town planning, or landscape design and refer to the human values, ideas, and beliefs that tangible elements exemplify.

It may be recalled that the World Heritage List has been conceived as a means of celebrating the monuments and sites of outstanding *universal* (transcultural) value as a follow-up to the salvage of the Abu Simbel Temple and other monuments of Nubia, in the context of the UNESCO mission for peace and intercultural understanding. However, heritage – as the cultural endowment handed down from preceding generations – may be conceptualized on the level of a nation, a society, or a community. Consequently, the sociocultural dimension embedded in the notion of heritage and the inherent attribution of heritage to a "group" of people necessitates not only a reconsideration of the types of tangible heritage but also the relationship between tangible and intangible heritage.

The material remains often selected as tangible heritage consist not only of buildings or groups of buildings, historical towns and gardens, and cultural landscapes but also of any objects or places which have been significantly modified by human actions. This includes objects made from a variety of materials (e.g., glass, textiles, stone, ceramics, metals, wood, paper) and locales such as quarries and rock art sites.

Evidently, the materials regarded as heritage are those deemed to be of *value* by a living group of peoples who *perceive* themselves as inheritors of that heritage. Accordingly what is regarded as tangible heritage is inseparable from an intangible intellectual value judgment. On an international level as in UNESCO, the community that makes the selection of items of "universal" value consists of experts working from their own professional traditions as architects, geographers, art historians, or archaeologists. By contrast, what is regarded as national heritage is often an expression of a state policy (that may or may not be representative of the nation). Thus, in this and other cases, tangible heritage, particularly monuments, is bound not only with a value judgment but also with an "objective." Castles, forts, palaces, and cathedrals and grand mosques signal state supremacy and the preeminence of religion and serve as nodes for symbolic actions, visits, performances, and literary discourses that perpetuate the socialization of people as national subjects and religious followers. On a community level, tangible heritage may be associated with tombs, religious shrines, or ancestral sites and objects. This multilevel conceptualization of heritage explains how in a modern nation state the

heritage of ethnic groups or minorities has been marginalized in favor of an "invented" (or "discovered") so-called "common" national heritage as a means for unifying the nation. Monuments, especially buildings; museums displaying certain collections; and specific places have been designed to proclaim national identity. In Europe, for example, tangible heritage in capital cities affirmed an affiliation with the Graeco-Roman civilizations. In modern Egypt, Cairo was redesigned to become a European city to forge a new identity at variance with the traditional "oriental" culture. In this period of cultural transformation (especially the nineteenth century), tangible heritage was intensively manipulated to create the current notion of "West" and "East" preparing the stage for the proponents of the clash of civilizations.

From another point of view, with the growing importance of tourism as an industry with profitable revenues, certain heritage elements were marketed as properties, commodities, and commercial assets. Although heritage is indeed a valuable resource for economic development, the economic exploitation of sites, museums, and buildings may undermine indigenous human development and disrupts existing social structures.

Tourism flourished after the advent of rapid means of travel, in the context of colonialism, industrialization, and a world divided between the industrial rich and the rural poor. As such, tourism engendered feelings of inequity on the basis of material differences in clothing and modes of transportation and places of residence between tourists and locals. It encouraged illicit digging and illegal sale of antiquities, and it favored the selection of specific elements of tangible heritage (exotic, grandiose, mysterious) as heritage icons. The linkage between tourism and "vacation" led to an emphasis on recreation and entertainment, contrary to the initial notion of tourism during the Enlightenment which centered on "cultural pilgrimage." In the making of our modern world, the role of tourism in manipulating tangible heritage can hardly be ignored.

The effect of tourism has also infiltrated academia as books by archaeologists and historians on treasures and TV series on "discoveries" and "adventures" abound. Here again, tangible heritage is selected and valorized through [intangible] narratives and practices. The objectives in this case are tinted with gaining wealth and fame.

The study of tangible heritage in academia suffers from other problems. Traditionally the study of archaeological or historical objects has focused on categorization, classification, and description with the aim of recognizing "periods" and "cultural areas." Although this has been superseded since the 1960s, with an emphasis on explanation and process, tangible heritage remains culturally under-theorized when it comes to how it articulates with the society it came from or how it can inform us of the role of tangible heritage in the making of history. Beyond an interest in tangible heritage for religious, aesthetic/artistic, technical (dating back to certain stages in the cultural evolution of Europe), is a new horizon for a new agenda, by which it can contribute to a culture of peace, reconciliation, cultural continuities, intercultural coevolution, and creativity. The latter requires a rethinking of "authenticity" and what it implies for a reinterpretation of tangible heritage as a source of innovation and renewal.

In sum, the notion of tangible heritage is inseparable from that of intangible heritage (previously called folklore, customs, and traditions). The previous neglect and current valorization of intangible heritage are related to changing sociopolitical conditions before and after the 1960s. However, tangible and intangible heritage are still regarded as separate categories given the disciplinary divide between those interested in tangible heritage (architects, archaeologists, geographers) and intangible heritage (folklorists). It is therefore crucial to recognize the intangible component of tangible heritage and the materiality associated with most intangible cultural heritage activities. The road ahead depends on how a new generation of scholars, freed from the restrictive fences of professional grounds and equipped with a comprehensive, dynamic view of heritage, will develop new interpretive and curatorial approaches that integrate tangible and intangible strands of cultural heritage elements and how they will contend with conflicts within and

between communities, nations, and international organization concerning the criteria of selecting heritage and why we need heritage in the first place.

Tanzania's History and Heritage

Ashley Sheriff
Independent Scholar, Urbana-Champaign, IL, USA

Introduction

Tanzania was founded on April 26, 1964, from the union between the former British protectorate of Tanganyika and the Zanzibar archipelago that consists of Unguja, also commonly called Zanzibar Island, and Pemba Island. After 42 years under British rule, Tanganyika gained its independence in 1961 and, similar to the former People's Republic of Zanzibar and Pemba, remained a sovereign state until the two independent countries signed the Articles of the Union treaty to create the United Republic of Tanzania. The second head of state and former Minister of Natural Resources and Tourism, Ali Hassan Mwinyi (1985–1995), reformed the failing economy from his predecessor Julius Nyerere's socialist administration by promoting the private sector, "free market forces," and export-producing businesses.

It was Mwinyi's reforms that encouraged the growth of tourism and heritage protection. The Ministry of Natural Resources and Tourism (MNRT) adopted the republic's first National Tourism Policy, and the Tanzanian Tourism Board (TTB) was established during Mwinyi's tenure as president. The MNRT oversees the nation's cultural and natural resources along with the tourism sector and enacts policies to ensure sustainable natural and cultural heritage management. The MNRT is charged with protecting Tanzania's cultural and natural resources and developing tourism. It is divided into five divisions: Antiquities, Fisheries, Forestry and Beekeeping, and Tourism and Wildlife.

The National Museum of Tanzania, an institution under the MNRT, is a consortium of five museums charged with "collecting, conserving, displaying and researching" Tanzania's cultural and natural history (MNRT 1999). The Museum and House of Culture's vision is to repurpose Tanzania's culture and heritage to create a "strong sense of value and pride" in current and future generations of Tanzanians. In concurrence with this mission, the museum boasts that the famous fossil skull of Australopithecus boisei "Zinj" in its collection is the pride of Tanzania. Dr. Louis Leakey and his wife discovered Zinj in 1959 at Olduvai Gorge, a ravine with numerous hominid fossils.

Key Issues/Current Debates/Future Directions/Examples

Mainland Tanzania

Northern Tanzania, together with southern Kenya, is known as Africa's "Safariland" (Salazar 2006). Over 28% of Tanzania's 945,234 km^2 is set aside to safeguard the country's rich natural heritage (Mabula and Bower 2010). This network comprises the Ngorongoro Conservation Area Authority (NCAA) based in Northern Tanzania and national parks including the often visited Serengeti National Park (SENAPA), with most of the protected land dedicated to game reserves and game controlled areas – 15% and 8%, respectively (Mabula and Bower 2010). In response to

the popularity of nature exploration and the "big five" African animals (Salazar 2006), Tanzania privileges nature preservation and wildlife conservation over cultural heritage management.

The 1964 Antiquities Act of Tanzania vested The Department of Antiquities with the ownership of Tanzania's "tangible cultural heritage resources" (Mabula and Bower 2010). Under the Act, the Director of Antiquities authorizes and manages tangible heritage resources and grants licenses to research heritage sites.

According to ICCROM's legal frameworks for the protection of immovable cultural heritage, the 1964 Antiquities Act of Tanzania vested The Department of Antiquities with the ownership of Tanzania's "tangible cultural heritage resources" (Mabula and Bower 2010). Under the Act, the Director of Antiquities authorizes and manages tangible heritage resources and grants licenses to research heritage sites. ICCROM's legal frameworks for the protection of immovable cultural heritage describe the 1964 Antiquities Act as the "basic legislation" mandating the protection of the following categories of cultural heritage: conservation areas, monuments, protected (ethnographic) objects, and relics. Under this Act, the Minister has the authority to place any area, object, or structure with cultural value under protection (Kamamba 2009).

The Act defines monuments as structures, carvings, incisions, paintings, or modifications to the earth made by humans before 1863 or the remaining ruins. Protected objects are Swahili-style wooden doors and doorframes dated before 1940 or, according to Kamamba, any object the Minister declares merits protection. Ornately carved nineteenth-century doors and doorframes symbolize artistic sophistication and wealth and are particularly at risk for being sold to tourists and hotels for their beauty (Sheriff 2001). A relic is any movable object including human, fauna, and floral remains that predate 1863 along with fossils and impressions produced by humans before 1863 (Kamamba 2009). The Act charges anyone who locates objects, relics, or sites that may be culturally significant with reporting their "discovery to the appropriate authorities" (Kamamba 2009), but this law is not stringently enforced, and instructions on legally handling cultural objects are unclear. Legal ambiguities allow the destruction, neglect, exploitation, or illegal selling of many heritage objects and sites.

Before commencing development projects, the Tanzanian government recognizes the importance of carrying out environmental impact assessments (EIAs); in fact both UNESCO and the World Bank require investors to conduct EIAs "to ascertain expected impacts on the environment . . . and to prevent destruction damage," but "Cultural Heritage Impact Assessments (CHIA) are not often conducted because they are "not explicit in Tanzania's cultural heritage legislation" (Mabula and Bower 2010). For example, the Ngorongoro Conservation Area Authority (NCAA) is in place to protect the area's rich natural heritage, but no equivalent organizations to safeguard archaeological heritage.

The Ngorongoro Pastoralist Project constructed an earth dam in 2000 in the culturally significant Laetoli site, only 2 km from the famous Australopithecine footprints. Laetoli has a rich deposit of early human and hominid fossils and artifacts – now compromised by rising water levels. The dam was built for the local Maasai to collect water for themselves and their livestock during the rainy season. The NCAA attempted to make the Laetoli hominids more visible and relevant to the local Maasai by inviting local officials, elders, and other community members to perform "a traditional ceremony to bless the site" (Mabula and Bower 2010). Gaining local support for such projects is often challenging because investing in cultural heritage management is often treated as a luxury and only considered after primary needs such as healthcare, food, and "political stability" are met (Mabula 2000).

The Ngorongoro Conservation Area, the only world heritage site in Tanzania categorized under UNESCO's "mixed" criterion with both outstanding cultural and natural heritage, attracts the most visitors of all the tourist destinations in the republic, and nearly 40% of foreign tourists visited the NCA in 2001 (Charnley 2005). The NCA was added to the UNESCO World Heritage List in 1978 as a natural heritage site and inscribed under the cultural criterion in 2010. In terms of natural heritage, this site contains the Ngorongoro

Crater, described by UNESCO to be the world's largest caldera (the collapsed mouth of a volcano), as well as Olduvai Gorge – home to nearly 25,000 animals (UNESCO n.d.) and one of the very most important archaeological sites in the world. This ravine contains the fossils of a series of modern human predecessors including, but not limited to, Australopithecus, Homo habilis, and Homo erectus; each hominid represents stages of human evolution spanning 4 million years. Archaeologists also found handmade tools and animal bones in the gorge; the tools are testaments to human ingenuity and the bones helped shape ideas about early hominid diets. Another noteworthy archaeological site located 45 km south of the gorge is Laetoli, famous for the three sets of bipedal Australopithecus afarensis footprints preserved in volcanic ash. Unfortunately Olduvai Gorge has fallen into disrepair because the fossils and museums have been neglected and vandalized. Grasses and acacia trees have grown over and endangered the Laetoli footprints (Mabula 2000), and although Olduvai Gorge brings in revenue (in 1998 nearly 39,108 tourists spent $60,000 in entry fees), little of the economic gain was reinvested into developing the site (Mabula 2000).

The Kondoa Rock Art cultural sites, added to the World Heritage List in 2006, are collections of painted images found in more than 150 shelters on the sedimentary rock formations that border the Great Rift Valley spanning more than 2336 km^2 (UNESCO n.d.); several of the rock sites have been repurposed as ritual sites by the nearby Maasai communities. According to UNESCO these sites "provide a unique testimony to the changing socio-economic base of the area from hunter-gatherer to agro-pastoralist, and the beliefs and ideas associated with the different societies." The Department of Antiquities does not have up-to-date records on the scope of paintings within these sites, so UNESCO encourages any surveys or assessments "to ascertain the scope of the site[s]" (n.d.).

The Ruins of Kilwa Kisiwani and the Ruins of Songo Mnara are on the World Heritage List (in 1981) as well as UNESCO's List of World Heritage in Danger in 2004. These cultural sites are the remains of two trading ports on islands near the coast (nearly 300 km south of Dar es Salaam) where goods such as gold, pearls, perfumes, and porcelain were sold from the thirteenth to the sixteenth century. Housing complexes, public squares, mosques, and domestic dwellings on the islands serve as a chapter in Swahili culture and architecture, "offering important insights regarding economic, social and political dynamics in this region" (n.d.). The Great Mosque of Kilwa Kisiwani is the oldest mosque on the East African coast. Although the two sites are protected under the Antiquities Act and a 2004 Management Plan, uncontrolled urban expansion, coastal damage by beach erosion, and inadequate conservation efforts have resulted in long-term threats.

The Central Slave and Ivory Trade Route was submitted by the Antiquities Department in 2006 as a testimony to the cruel treatment of African slaves in Central and East Africa, including Tanzania. Slaves were held on the coast and many times sent to Zanzibar and then sold to Arab countries. The recommendation for this site to be inducted into the World Heritage List is based on engaging the tragic history of the slave trade, preserving the visible, physical reminders of this trade route remain in Tanzania's landscape and researching and documenting the "memories" of human suffering and enslavement to preserve the cultures and traditions of the people who live along the trade route (UNESCO n.d.).

Zanzibar

The Stone Town of Zanzibar is Zanzibar's most popular attraction. The town is a large, well-preserved former slave-trading port on Unguja Island that was inscribed in UNESCOs World Heritage List in 2000. The stone town of nearly 2000 buildings is noteworthy for its historic urban landscape developed from more than two centuries of Swahili, Portuguese, Arabic, and Yemeni cultural influences and architectural traditions (Mohamed 2001; Sheriff 2001). UNESCO describes the Stone Town as an example of cultural fusion as its architecture demonstrates the melding of African, Arab, and European cultures. This site is characterized by survivals of Portuguese churches and forts, and Islamic mansions that were eventually "amalgamated and homogenized into a characteristic [vernacular] Swahili architecture" and over time influenced by new styles brought by immigrants to Zanzibar (UNESCO n.d.)

In 2009 the Flemish government helped coordinate and launch a series of historic urban landscape (HUL) workshops on Africa's east coast by introducing HUL to governments and host communities in "World Heritage-designated cities" including the Stone Town of Zanzibar. These workshops are to include training for government officials and the community at large on urban landscape conservation and facilitators to promote research for the development of a "toolkit for urban conservation," revisiting the groundwork of the 1972 World Heritage Convention for establishing urban development, and "management of the World Heritage Cities Programme" (UNESCO n.d.). Domestic as well as international agencies are vested in the Stone City. The Zanzibar Stone Town Heritage Society "Jumuiya Ya Uhifadhi Mji Mkongwe" is an NGO established in 2002. The society's mission is to promote the conservation of the Stone Town's heritage, environment, and the "cultural welfare of its inhabitants" (2010); it works towards this mission with a list of objectives that include raising awareness of the Stone Town's conservation concerns, and, similar to UNESCO's HUL workshops, the society provides community outreach activities, training, services, research, and technical support to improve the Stone Town's urban landscape. The society also lobbies for conservation policies and builds relationships with other organizations interested in conservation.

Taphonomy in Bioarchaeology and Human Osteology

Shari Forbes
Centre for Forensic Science, University of Technology Sydney, Sydney, NSW, Australia

T

Introduction

Classical Taphonomy

Traditionally, taphonomy was studied by paleontologists to interpret the processes that operate on organic remains that comprise a part of the fossil record. A major focus of taphonomy was to understand the effects of those processes in order to reconstruct the past as it pertains to a particular fossil assemblage (Shipman 1981).

Years later, archaeologists began to study taphonomy in order to determine how and why floral and faunal remain accumulated and differentially preserved within the archaeological record. Interpretation of the postmortem, pre-, and post-burial histories of faunal assemblages is critical in determining their association with hominid activity and behavior. Archaeologists typically separate natural from cultural processes when identifying evidence of human interaction with faunal remains (Lyman 1994).

Various models of fossil assemblage formation have been proposed, depicting a general taphonomic history. The *taphonomic history* defines the chronology of taphonomic agents and processes affecting the faunal remains and may include a cyclic sequence of events (e.g., a bone may be buried, exposed, gnawed, transported, and reburied). A *taphonomic agent* refers to the source of modification to the faunal remains (e.g., hyena), while a *taphonomic process* describes the dynamic action of that agent on the remains (e.g., gnawing). The *taphonomic effect* is the result of a taphonomic process (Lyman 1994). The basis of taphonomy is therefore the qualitative and, where possible, quantitative analysis of the taphonomic effects, processes, and agents acting on carcasses and skeletal tissues.

The geological context in which faunal remains are discovered and their distribution in the stratigraphy may provide important information about the paleoenvironment and formation of the site. However, information about the taphonomic history of faunal remains comes specifically from the recovered animal carcasses and skeletal tissues (Shipman 1981). Postmortem processes affecting skeletal remains, and subsequently the state of preservation of the bone, reflect the sequence of taphonomic events which comprise the taphonomic history. An understanding of the taphonomic history of faunal remains aids archaeologists in explaining their interaction with prehistoric human populations (Micozzi 1991; Lyman 1994).

Figure 1 provides an overview of the transformation from living organism to fossil (based on Behrensmeyer and Kidwell 1985; Martin 1999).

Organisms must pass through three distinct and separate stages to become a part of the fossil record. These stages span the time frame from death to discovery and/or recovery. The first stage involves the death or loss of a part of an organism and is referred to as necrology. Necrology can be denoted by T_0 and represents the initial stage of the taphonomic history. Processes that occur from death through to burial represent the second stage and are referred to as biostratinomy. These processes result from reworking and destruction of the remains and may include decomposition, scavenging, bioturbation, and postmortem transport. The third stage is termed diagenesis and refers to the physical and chemical processes occurring after burial. Diagenetic processes result in the transformation of organic material to mineral in sediments and include dissolution, leaching, and recrystallization (Micozzi

Taphonomy in Bioarchaeology and Human Osteology, Fig. 1 Transformation stages from living organism to fossil. (Based on Behrensmeyer and Kidwell 1985; Martin 1999)

1991). Mineralization will only occur if the natural decay process does not lead to complete destruction of the remains (Allison 1990). This process allows for the discovery of preserved material in the archaeological record, whereby T_1 represents the time of discovery.

One of the many challenges of taphonomic analysis is to identify the processes and agents acting on the remains during the time frame to fossilization (i.e., $T_1 - T_0$). The postmortem factors that can act on faunal remains are numerous and include physical, chemical, and biotic agents (Brett 1990; Ubelaker 1997). Broadly speaking, the destruction of a skeleton can be categorized sequentially as follows (Brett 1990): (1) disarticulation, (2) fragmentation, (3) abrasion, (4) bioerosion, and (5) corrosion and dissolution. Disarticulation occurs through the postmortem action of enzymes and bacteria in the organism leading to the biochemical breakdown of tissues including connective tissues and ligaments. When this degradation occurs along pre-existing joints or articulations, the skeleton becomes disarticulated naturally. Biotic agents such as scavengers and faunal burrowers can physically accelerate disarticulation through their actions. Physical agents such as water currents and turbulence can also result in disarticulation of skeletons that have commenced the decay process (Brett 1990). Fragmentation can result from physical factors such as rock fall, weathering, burial, shockwaves, diagenesis, and cryoturbation, as well as biotic animal-related processes including trampling, gnawing, and digestion (Marshall 1989; Micozzi 1991). Abrasion involves physical grinding and/or polishing of skeletal elements causing a rounding of their edges and loss of detail. The extent of abrasion will be highly dependent on the sedimentary environment and particularly the particle size of the abrasive agent. Bioerosion is seen most commonly in shallow marine environments, while corrosion and dissolution are commonly observed in seawater or in sediment pore waters through the action of bioturbation. Dispersal and postmortem transport of remains may also involve animals or may result from gravity or fluvial processes. Discriminating between nonhuman and human agents of bone modification with respect to human subsistence patterns involves analyzing taphonomic factors such as scavenging, hunting, butchering, and transport of prey (Bonnichsen and Sorg 1989).

Forensic Taphonomy

Many of these taphonomic processes are also important in the analysis of more recently skeletonized remains. As a result, the principles of taphonomy are now utilized in the field of forensic science. Forensic taphonomy involves the use of taphonomic models and approaches to estimate time since death, reconstruct the events surrounding death and before and after burial, and discriminate between bone modifications resulting from human behavior and those caused by the earth's physical, chemical, biological, and geological processes (Haglund and Sorg 1997; Ubelaker 1997; Schotsmans et al. 2017). Due to the multidisciplinary approach required in a forensic investigation, forensic taphonomy may encompass experts in anthropology, archaeology, soil science, palynology, and many other disciplines based on the particular requirements of the crime scene. The main goal of applying taphonomic investigations to a crime scene is to assist with locating, recovering, and identifying human remains, as well as estimating the postmortem interval and determining the cause and manner of death (Schotsmans et al. 2017).

In a forensic context, taphonomy is used to define all events acting on human remains between death and discovery. This time frame (i.e., $T_1 - T_0$) will be considerably shorter for forensically relevant remains when compared to remains of paleontological or archaeological significance. Due to the shorter time frame of forensic investigations, forensic anthropologists are concerned with soft tissue decomposition rates and patterns, in addition to bone modification, disarticulation, and dispersal (Haglund and Sorg 1997). Postmortem decomposition varies considerably between geographical regions and can also demonstrate significant variation across and within microenvironments (Ubelaker 1997). It is important to recognize that both intrinsic and extrinsic factors can impact the rate and process of tissue decay. Intrinsic factors result from the

physiology of the individual at the time of death, including age, gender, body mass, physical health, and modifications such as the ingestion of medications. Extrinsic factors may result from the depositional environment such as water, soil, temperature, oxygen, flora, and fauna or from human behavior such as the cause of death, body deposition, and other modifications such as dismemberment and treatment with chemicals or through the action of burning (Schotsmans et al. 2017). Consideration must be given to all of these parameters and many more when interpreting the taphonomic history of human remains in a forensic investigation.

Definition

Taphonomy is the study of the transition of organic remains from the biosphere into the lithosphere as a result of geological, biological, and chemical processes which act on the remains (Shipman 1981; Lyman 1994; Martin 1999). The science of taphonomy has been practiced for centuries. However, the term "taphonomy" was first defined by Russian paleontologist, I.A. Efremov (1940), to denote a subdiscipline of paleontology which studied the events that occur between death and fossilization. The term was derived from Greek roots *taphos*, meaning burial, and *nomos*, meaning laws (Micozzi 1991; Lyman 1994; Martin 1999).

The definition of taphonomy has since been extended to incorporate the study of bone accumulation and modification from a site formation perspective (Bonnichsen and Sorg 1989) and interpret the life history of a fossil from the time of death to the time of recovery (Olson 1980). The latter definition recognizes the importance of understanding the circumstances surrounding the event and the time since death or deposition.

Key Issues and Current Debates

Early Taphonomic Research

Taphonomic research in the fields of paleontology and archaeology has predominantly been directed toward reconstructing paleoenvironments, identifying factors which cause destruction or modification of bone, understanding dispersal and transport of remains, and discriminating between nonhuman and human agents of soft tissue preservation and bone modification (Haglund and Sorg 1997).

A key issue and one of the major foci of taphonomic research is to understand the biases inherent in the fossil record. A major bias is the lack of organic soft tissue preserved over time and subsequently recovered. Given the percentage of soft tissue found on many organisms, the natural and rapid decay of this material can represent a significant bias in the recoverable data which is predominantly hard or mineralized tissue (Allison 1990). When interpreting a fossil assemblage, it is necessary to determine how that collection of skeletal remains was derived from the animal community that once populated the area. Since not all animals, and even fewer plants, are preserved through time, the fossil record provides an incomplete picture of the original ecosystem. Where organic remains are recovered, this typically occurs in an exceptional preservation environment such as the recovery of "bog bodies" in Northern Europe. These conditions, while ideal for soft tissue preservation, can often lead to the dissolution of other parts of the organism such as hard tissue. The bog bodies provide an excellent example, whereby the skin, muscle, and hair were exceptionally well preserved but the body-like structures often lacked bones and other hard parts (Allison 1990).

The process of recovering faunal remains is also a biasing factor. Researchers may affect the assemblage by differentially sampling, collecting, and recording the data based on personal observation and expertise. Archaeologists must therefore be aware of the taphonomic significance of the stratigraphic and sedimentary context of faunal remains when sampling (Lyman 1994).

When the term was first defined, Efremov (1940) determined that the study of taphonomy would focus on four major problems encountered in paleontology. First, the state of preservation of fossils is often poor and the number of skeletons few, due to the increased destruction experienced

over time and the variations in the size of fauna sampled. Second, a faunal assemblage may not have been associated in life but rather may have accumulated accidentally either at death (known as thanatocoenose) or after death (known as taphocoenose). Third, the appearance of a presumably new fauna without identifiable ancestors in the site formation may not necessarily represent a new group of species as ancestral species may not have been preserved under the prior environmental conditions. And finally, the preservation of species and skeletal elements will vary in different sedimentary environments, and assemblages may not resemble the same species due to fossilization of a select sample of the original community (Shipman 1981).

For many years, it was incorrectly assumed that a fossil record was a snapshot of an animal community which had been preserved through the processes of fossilization. Taphonomic studies have assisted in reducing the assumptions once made about fossil assemblages. It is now understood that animals do not necessarily die in the environment within which they lived and that an abundance of one fossilized species in the fossil record does not represent an abundance of that species in the original community.

It is no longer assumed that two species found in the same assemblage lived together in the same environment or that the lack of a species in an assemblage represents their rarity or absence in the original community (Shipman 1981). By studying taphonomic data and observing taphonomic patterns, paleontologists and archaeologists are now able to provide more meaningful interpretations of the fossil record.

Recent Taphonomic Research

During the period 1970–1986, the field of taphonomy expanded beyond the focus on bias and placed a strong emphasis on actualistic, process-oriented research. Scientists recognized that the original definition of taphonomy failed to encompass the broader focus of how fossil assemblages change during preservation as a result of both the addition and loss of information (Behrensmeyer and Kidwell 1985). Behrensmeyer and Kidwell proposed a new definition for the field as "the study of processes of preservation and how they affect information in the fossil record" (Behrensmeyer and Kidwell 1985: 105).

During this same period, actualistic studies between life and death assemblages became important, and the processes of death and decomposition were extensively studied by Behrensmeyer and colleagues in African terrestrial environments (Behrensmeyer 1978; Behrensmeyer et al. 1979). Despite the difficulties experienced in reconstructing the past using fossil assemblages, their studies demonstrated that modern bone assemblages can resemble the living animal community (Behrensmeyer et al. 1979). This new perspective led to research in middle-to-large-scale taphonomic phenomena and the dynamic interactions between biological and geological processes.

After decades of taphonomic research and much debate, the following rules are generally accepted as empirical principles of taphonomy (based on Martin 1999) but by no means represent a complete list.

1. An organism is more likely to be preserved if it comprises hard parts.
2. Preservation is considerably enhanced if the remains are rapidly buried in fine-grained sediment.
3. Preservation is considerably enhanced in the absence of decomposition and scavengers.
4. Chemical and physical destruction resulting from decay, abrasion, transportation, predation, scavenging, and dissolution will cause a loss of information about community structure and species abundance.
5. Taphonomic information loss in terrestrial and fluvial environments predominantly results from transport, disarticulation, and breakage by water, predators, scavengers, trampling, etc.
6. Bioturbation and physical alteration preferentially mix sediments upward causing temporal mixing of different communities and leading to an increased diversity in morphological features of fossil ancestries.
7. Taphonomic transformation can lead to information gain for reconstructing the environment and past community dynamics.

8. Catastrophic burials (e.g., Lagerstätten – fossil deposits demonstrating remarkable diversity or preservation) are valuable for providing a snapshot of the population dynamics but are not representative of the temporal variation in populations.

Since taphonomic processes can act on biological remains during the period of death and discovery, it is recognized that some skeletal remains may survive better than others with time. The ultimate goal of taphonomy is thus to identify and quantify the biases associated with the process of fossilization to allow for accurate interpretations of the relative abundance of organisms in a fossil assemblage.

Forensic Taphonomic Research

Taphonomic research in the field of forensic taphonomy faces additional challenges in deciphering the effects of human behavior on human remains since that behavior can impact the cause and manner of death as well as the rate and biochemical processes of decomposition and/or preservation. The structural differences between human remains and nonhuman remains will cause variation in their response to taphonomic agents. In addition to analyzing the taphonomic effects such as weathering, gnawing, and trampling, forensic anthropologists must also interpret the effects of cultural processes such as embalming, burial, and cremation (Ubelaker 1997).

While the forensic anthropologist may draw parallels with some of the principles of paleotaphonomy (e.g., Behrensmeyer's (1978) stages of bone weathering), many of these effects must be individually studied on forensic remains in order to understand their taphonomic impact. One of the main challenges in forensic taphonomy today is understanding how postmortem changes to human remains will affect the estimation of time since death. The range of intrinsic and extrinsic factors that can act as taphonomic agents means that no two sets of remains will decompose in the same way even when placed in the same environment, further adding to the challenge of using the rate of decay to estimate this time frame. Research in this complex area has many complications, but advances are being made by researchers employing observational and experimental taphonomic studies in a range of forensic environments. Until recently, the utilization of donated human cadavers for forensic taphonomic research was limited to a select few facilities in the USA (Vidoli et al. 2017). More recently, additional facilities have opened in Australia and the Netherlands, and there appears to be an increase in interest in establishing human taphonomy facilities in many regions of Europe and the UK. Such facilities will allow forensic taphonomic studies to advance beyond the use of animal analogues and provide a greater understanding of the taphonomic history of human remains in our local environments (Forbes 2017).

Future Directions and Examples

Over the past two decades, process-based research has provided a valuable understanding of the taphonomic bias in modern environments. However, a key issue that remains is the extent to which taphonomic bias varies with time. Much research has gone into understanding how the taphonomic bias varies with depositional environment (Schotsmans et al. 2017), but there is little understanding of how this same bias has changed through time, although there are examples that it potentially has (Allison and Bottjer 2010).

Examples of biomolecular and biological evolution highlight the fact that some organic remains and skeletons are more likely to preserve than others and that this has changed over time. The evolution of burrowing organisms can alter taphonomic bias by disturbing and potentially degrading faunal remains buried in the sedimentary environment, as it has been shown that the depth of burrowing has increased with time. Additionally, fossil Lagerstätten represent snapshots of preservation that clearly demonstrate temporal variation in fossilization (Allison and Briggs 1991).

Fossil Lagerstätten refer to rare fossil deposits which have undergone exceptional preservation and include evidence of soft tissues. This concept was first popularized by Seilacher's group at the University of Tübingen (Behrensmeyer and Kidwell 1985; Allison and Bottjer 2010) and led to extensive efforts to investigate current and new

Lagerstätten. Research in this area focused on understanding the taphonomic processes leading to exceptional preservation of soft tissue which advanced a new field of experimental taphonomy. Fossil Lagerstätten represent unique but excellent examples of preservation in the fossil record.

Taphonomic research now benefits from a diversity of approaches including field, laboratory, and database studies. Allison and Bottjer (2010) predict that database studies will be more frequently used in the future but also highlight the need for ongoing field studies to populate those databases. They propose that the major gaps still remaining in taphonomic knowledge relate to Precambrian taphonomy, organic geochemistry, and global biodiversity. Future research in these fields will help to elucidate a better understanding of the early history of Earth, the pathways between organic molecules and the preservation of organic carbon, and the impact of mass extinction events on taphonomic processes.

Although the field of taphonomy is now considered to be well established, the field of forensic taphonomy is still in its infancy. During the past two decades, considerable advances have been made in forensic taphonomy (Micozzi 1991; Haglund and Sorg 1997; Schotsmans et al. 2017). However, further research is required to understand the effect of taphonomic processes and agents on soft tissue and hard tissue in the numerous environments in which decomposition can and does occur. The random nature by which many crimes are committed means that almost any environment can be utilized to dispose of human remains. These environments must continue to be the focus of taphonomic studies to assist forensic anthropologists in accurately understanding the processes of tissue decomposition and preservation.

Taphonomy in Human Evolution

Jessica C. Thompson
Department of Anthropology, Emory University, Atlanta, GA, USA

Introduction

Taphonomic research is essential for the interpretation of fossil plant or animal assemblages that are recovered from early archaeological sites. Within human evolutionary studies, it provides a way to reconstruct past processes that have acted on fossil assemblages of direct relevance to our understanding of early hominin and early modern human behavior. Taphonomic research may be applied to the fossil remains of human ancestors themselves, the remains of the animals and plants that were part of their ecological surroundings, or the material remnants of their behavior (e.g., the discarded remains of their meals). Without taphonomy, the many processes that can operate on an assemblage over the long time periods represented by the human evolutionary record could not be reliably untangled.

Taphonomic processes are typically viewed as reductive and destructive, taking away information from a complete picture of the forms and ecologies of living things in the past. However, taphonomic processes can also add information about the circumstances of deposition and subsequent modification of what are now fossil remains. Each intervening taphonomic process that alters a fossil or an assemblage also has the potential to leave a trace, thus allowing information about the processes themselves to be reconstructed. This kind of research has sparked several debates within human evolutionary studies, leading to the interpretation and reinterpretation of some of the most significant early sites over the course of the last four decades.

Definition

Taphonomy in human evolution is taphonomic research mainly used to aid interpretation of the subsistence behavior of early humans and our ancestors. In this context, it is most often used in reference to fossil animal bones. However, it may also be applied to hominin bones to discover how they came to rest in a given context, or it may be used to interpret other remains that are of relevance to understanding the behavior of ancient human relatives or their ecologies.

Historical Background

Key Historical Figures

Charles K. (Bob) Brain was a pioneer in taphonomic research within a human evolutionary framework. In the 1960s, he used observations of how dogs modified bones discarded by people to formulate ideas of what this would look like in

the fossil record. He later (Brain 1981) wrote a book entitled "The Hunters or the Hunted?" in which he used these observations to interpret the faunal assemblages from Sterkfontein and other early hominin-bearing cave sites from South Africa. Previously, the fossil animal bones from these sites were thought by authors such as **Raymond Dart** to have been either food debris or even weapons used by early hominins such as **australopithecines**. Brain's taphonomic work debunked many of these ideas by demonstrating that in fact the majority of the fossil remains – including the remains of hominins – were the result of carnivore predation (Fig. 1). This interpretation has stood the test of time and is currently still accepted as the most parsimonious explanation.

In the same year, another landmark book was written by **Lewis R. Binford** (1981), entitled *Bones: Ancient Men and Modern Myths*. Binford argued that within Paleolithic research, many of the interpretations about how fossil faunal assemblages were formed were made post hoc, resulting in the perpetuation of unevaluated "myths" about the past. He had spent several years studying how modern hunter-gatherers obtain and discard faunal remains, with a particular focus on understanding how bone accumulations at archaeological sites are created. He also noticed that such accumulations may be modified or independently created by nonhuman processes, such as carnivore denning and scavenging. Binford used these observations to stress the importance of applying **Middle-Range Theory** to link interpretations of the past directly to observations made in the present. This theoretical framework continues to play an essential role in taphonomic research today.

Taphonomy in Human Evolution, Fig. 1 The classic illustration by Dr. C.K. "Bob" Brain of a fossil hominin skull exhibiting two puncture marks that fit the tooth spacing of a fossil leopard found at the same site. Image courtesy of the Ditsong National Museum of Natural History

Development of Actualistic Research as an Interpretive Framework

The experiments and observations performed by Binford and Brain are, respectively, examples of **ethnoarchaeology** and actualistic research. Such research is performed under the uniformitarian assumption that modern processes we observe today also happened in the past. Therefore, by the observing the traces or impacts certain behaviors leave in the modern day, one can infer that the same behaviors also caused similar traces or impacts on fossil assemblages in ancient times (Fig. 2).

Within human evolutionary studies, actualistic taphonomic research has taken three major forms: basic experimentation, naturalistic experimentation, and ethnographic observation. Basic **experimental archaeology** offers the most control to the researcher. Bones or other objects of interest are subjected to taphonomic processes under simulated conditions where a wide variety of variables can be known and manipulated. Naturalistic experimentation is similar, except that the bone or other object of interest is introduced into a natural setting and the transformation it undergoes is observed more passively as several variables within the system may operate simultaneously upon it.

Arguably, modern hunter-gatherers are not a perfect analogue for all early archaeological sites, which have been created by a range of hominins in the genus *Homo* and potentially other genera such as ***Paranthropus***, *Australopithecus*, or *Kenyanthropus*. However, ethnographic observation of how living humans acquire, process, and discard bones does provide essential information on human decision-making and archaeological **site formation processes**. Notable examples that have been applied to the human evolutionary record are Binford's (1981) book, which drew heavily on his experiences with

Taphonomy in Human Evolution, Fig. 2 An actualistic study in progress. The image above shows some goat bones laid outside a camp on the Serengeti Plain, Tanzania, just after dark. The image below shows those same bones just before dawn. Hyenas were heard through the night, and almost all of the bones have disappeared, leaving a few small shaft fragments. From this, similar degrees of ravaging might be expected at ancient sites

the Nunamiut of Alaska, and the work of Bunn et al. (1988) with the Hadza of the Eyasi Basin of Tanzania. All three forms of actualistic research and ethnoarchaeological work have underlain some of the largest debates in zooarchaeology and taphonomy as they have been executed in a human evolutionary context. In all cases, major changes in site interpretation have been inextricably intertwined with challenges to the existing methodological status quo.

Key Historical Debates: Hunting Versus Scavenging

The ability to regularly acquire meat and fat from large animal sources was an important watershed in the diet and behavior of our ancestors. Prior to the actualistic work that became prominent in the 1980s, it was frequently taken for granted that if fossil animal remains were found in association with stone artifacts, then the fossils were also there as the result of hominin activity. A famous example is the FLK Zinjanthropus, or "Zinj" site at **Olduvai Gorge**, Tanzania, which dates to approximately 1.84 million years ago. Excavations in the 1960s by Mary **Leakey** revealed a rich and well-preserved fossil faunal assemblage in association with stone artifacts, which was interpreted by many archaeologists as evidence that the site was a "home base" or "living floor" used by early hominins. Binford's (1981) book took this assumption to task, concluding on the basis of bone breakage and skeletal part representation that there was little evidence of the site being used as a home base, analogous to a modern hunter-gatherer camp. Binford argued that the bone accumulations in association with stone tools could be explained simply by hominins scavenging after carnivore kills.

Subsequent researchers such as Shipman and Rose (1983) emphasized the use of microscopic techniques to reliably identify signatures of hominin modification such as cut marks from stone tools. They further cautioned against the assumption that bone accumulations such as that at Zinj represented the remains of hunted meals. However, when Bunn and Kroll (1986) reanalyzed the assemblage they argued that both skeletal element abundances and bone surface modification suggested that early hominins were actually capable of hunting large mammals and bringing them back to particular sites on the landscape to be butchered. This debate became known as the "Hunting versus Scavenging" debate.

In a naturalistic study conducted in Serengeti National Park, Blumenschine (1988) simulated a series of "hominin-first" and "carnivore-first" scenarios by leaving bones for scavenging by wild hyenas. Both hominins and carnivores would have broken bones for the fat-rich marrow inside, but the study showed that they would have left different traces on the bone surfaces when they did so, and in different proportions. When hominins were first, there would have been more hammerstone percussion marks and when carnivores were first, there would have been more carnivore tooth marks. When applied to the Zinj assemblage, the large numbers of tooth marks suggested it had been heavily modified by carnivore activity. The implication for human evolutionary studies was that our earliest tool-using ancestors would have only gotten access to meat and marrow through scavenging.

The case seemed to have been closed, until Domínguez-Rodrigo and Barba (2006) introduced a new element to the debate. They argued that full account had not been taken of other agents that can produce marks on bones. Specifically, fungus and bacteria can etch bone surfaces in such a way that they may resemble tooth marks – thus leading to an overestimate of the role carnivores had in modifying the assemblage. Again they turned to the Zinj assemblage as an example.

The debate is not yet settled, with a new generation of taphonomists now arguing that the evidence for scavenging at the site is still stronger than any evidence of early hominins having first access. Although most researchers doubt that early **Oldowan** tool-using hominins such as ***Homo habilis*** were as proficient at hunting as modern humans, no agreement has been reached about how all the bones came to be accumulated at Zinj. However, the debate has spurred the development of taphonomy forward as a discipline by demanding new and more rigorous interpretive models, experimental designs, and actualistic analogues.

Key Historical Debates: Hunting Proficiency of Early Humans

Taphonomic research has also been instrumental in investigations not just of the origins of hunting per se, but the origins of modern hunting ability. The **modern human origins** debate began to escalate during the 1980s as researchers sought to understand when, where, and how our species first emerged sometime after about 400,000 years ago, only to later disperse around the globe. The debate has since encompassed both the fossil hominin and archaeological records, with archaeologists focusing on uncovering evidence of the origins of modern human behavior, including subsistence. Because fossil animal bones are some of the most commonly preserved material remnants of subsistence behavior, much of the focus has been on large **zooarchaeological** assemblages from early modern human sites such as Klasies River Mouth in South Africa. Part of the debate also revolved around questions of the subsistence behavior of our extinct close relatives that were not anatomically modern; for example, the **Neanderthals** in Europe.

Initial work by Klein (1975) at Klasies River Mouth suggested that early people were able to hunt some animals, but not the most dangerous ones. This was based on straightforward interpretation of faunal abundances at the site, which showed that more dangerous animals such as Cape buffalo (*Syncerus caffer*) and bushpig (*Potamochoerus porcus*) only became common during the Later **Stone Age**, which variably dates to between 20,000 and 40,000 years ago across the African continent. Again, Binford (1984) had a different interpretation. He proposed

instead that most of the faunal remains at Klasies showed evidence of being scavenged by people and that early anatomically modern humans could not have been adept hunters at all. Because no modern hunting and gathering group is known to purely obtain meat through scavenging, interpretations such as these set up a dichotomy between the evolution of modern anatomy (which was already in place) and modern behavior (which was interpreted by Binford to have evolved later).

Stiner's (1994) study of the faunal remains from Neanderthal sites in Europe also suggested that Neanderthals periodically used scavenging as a primary mode of meat acquisition. A major component to the interpretations by all these researchers was the fact that primary meat-bearing limb elements were uncommon relative to head-and-foot elements at each of the sites they had identified as containing scavenged assemblages. The reasoning was that head-and-foot elements represent the nutritionally poor "leftover" carcass portions and that a hunted assemblage should contain higher abundances of meaty limb parts. Before the scavenging interpretation, the common head-and-foot pattern had been explained by the "schlepp effect," which was based on an intuitive interpretation ungrounded in either ethnoarchaeology or actualism that hunters would cut meat from bones, lay it on a hide, and then "schlepp" it back to a home base with the foot bones still intact. Stiner's work challenged the schlepp effect, but this challenge soon came under fire itself when a third possibility emerged.

Marean and Kim (1998) noted that sites in Stiner's sample that exhibited the strongest head-and-foot patterns were the same sites that had been excavated when it was not common practice to analyze or sometimes even retain long bone shaft fragments. They also noted similar problems with other sites that had been studied by Binford and Klein – including Klasies River Mouth. The rationale for discarding long bone shaft fragments was that they are not taxonomically diagnostic and can even be difficult to place on a specific skeletal part. Therefore, excavator bias may explain why meaty long bones appear to be missing from sites where long bone shaft fragments were not studied. This interpretation rests on one key observation: that long bone abundances cannot be reliably reconstructed from the more taxonomically identifiable long bone end portions, which were consistently kept and counted (Fig. 3).

In Marean et al.'s (1992) basic experimental study on hyena ravaging of modern bone assemblages in a captive setting, they found that hyenas preferentially consume greasy skeletal elements or element portions compared to other portions, such as dense long bone shafts. Therefore, an archaeological assemblage that has been ravaged by hyenas – or by extension other bone-modifying carnivores – would be expected to have most of the limb elements represented by shaft fragments rather than the greasy (but unfortunately more taxonomically diagnostic) end portions. At sites where shaft fragments had been preferentially discarded by the excavator, most of the remaining evidence for meat-bearing limb bones would have been discarded with them. Without the shaft fragments available, the observed "head-and-foot" pattern could be explained equally by carnivores scavenging after hominins or by hominins scavenging after carnivores. This sparked a debate about the role of bone density in the preferential destruction of certain skeletal parts that was still being joined by researchers such as Pickering et al. (2003), over a decade after the original hyena study had been published.

Since the early 2000s, the debate has cooled, and an array of research has been conducted at other South African early modern human and European Neanderthal sites of similar or even older age. When complete assemblages are used for analysis and bone surfaces are scrutinized for evidence of hominin butchery, the taphonomic research shows that both hominin species enjoyed early access to carcasses. Both were also likely adept hunters of large ungulates, although they may have used different apparatus to do so. The emphasis of current research is now on exploring the variability that existed within subsistence strategies during this time period and using taphonomy to untangle the specific depositional histories of bone accumulations at these sites.

Taphonomy in Human Evolution, Fig. 3 Generic template of the left femur of an ungulate showing differences in preservation between the shaft and the ends. All femoral fragments drawn onto the image were recovered from the South African cave site of Pinnacle Point Cave 13B, which is partially contemporaneous with Klasies River Mouth. Darker areas represent parts of the bone that have several specimens representing that portion, red striped areas (with arrows) indicate the portions with the most preserved specimens, and pink spotted areas indicate regions that are not represented at all in the assemblage. In this case, twice as many individual left femora are represented by the shafts as by the ends. This is apparent in the MNE, or Minimum Number of Elements, represented by each part

Key Issues/Current Debates

Current Debates: Origins of Hominin Meat-Eating Behavior

Despite the interpretive strength offered by actualistic research, it is not always a straightforward matter to apply it to a fossil assemblage. It is commonly the case that one taphonomic process may imprint over another, and ancient bones have had a lot more time to be exposed to different processes than modern bones. More dangerously, some processes result in equifinality in fossil assemblages, whereby different pathways produce the same end result. In these cases, the many potential processes leading to the point at which a fossil is studied cannot be reliably reconstructed, and this can have a major impact on the overall behavioral interpretation of a site. This problem has lain at the root of historical debates about hunting versus scavenging and early modern hunting behavior. It continues to instigate debate today.

One of the key lines of evidence researchers have used to argue for or against the presence and timing of hominin butchery at fossil sites is bone surface modification (Fig. 4). Cut, percussion, and tooth marks were initially all thought to be diagnostic of either hominin or carnivore activity. The timing of carcass access was thought to be able to be directly read from relative proportions of these marks or by the locations or intensities of these marks. For example, cut marks superimposed over tooth marks could be taken as evidence of hominins scavenging after carnivores and the reverse could also be true for tooth marks superimposed over cut marks. The ongoing debate about hunting and scavenging at Olduvai Gorge exemplifies how any change to the relative proportions of different kinds of marks can have an enormous impact on site interpretation.

This principle of using bone surface modification in taphonomy hinges on the ability of researchers to accurately tie a trace on a fossil to its underlying cause. Fossils are found in a variety

Taphonomy in Human Evolution, Fig. 4 Examples of bone surface modification on fossils, showing the potential overprinting of taphonomic processes in sequence from negligible to extreme: (**a**) a bisected pit filled with matrix thought to be typical of crocodile modification on a fossil specimen from the Ledi-Geraru study area in Ethiopia; (**b**) a cut mark that has been partially erased by rodent gnawing from Sandia Cave, New Mexico; (**c**) a cut mark that has been completely covered by a percussion mark (fine striations) from the site of Blombos Cave, South Africa; and (**d**) a cut mark that has been extensively covered by root or fungus etching and emplacement of matrix from the Loiyangalani site in Tanzania

of depositional contexts, and the number of possible processes that can damage their surfaces is overwhelming and often site-specific. In the 1980s, there was much debate over the best criteria (microscopic and macroscopic) one could use to confidently identify cut marks. Behrensmeyer et al. (1986) showed that even cut marks, which were thought to be diagnostic of stone tool-wielding hominins, may be mimicked by natural processes such as trampling. Such uncertainties have led to some of the most heated debates in archaeological research pertaining to early hominin diet, and over the last decade many of the debates from the 1980s have been resurrected in the context of both old and new discoveries.

In 2010, McPherron et al. reported two fossil specimens from the Dikika DIK-55 site in the Afar region of Ethiopia that bore 12 surface modifications interpreted to have been caused by hominin butchery with stone tools (Fig. 5). The two specimens, dated to ~3.4 million years ago, predated the earliest flaked stone artifacts known at the time by more than 800,000 years, suggesting that taphonomic analysis – rather than stone tools themselves – might be the best way to reveal the earliest evidence for tool-assisted subsistence behavior in the archaeological record. Furthermore, if the marks were produced through butchery, it would mean that hominin exploitation of large animal meat and fat resources – and the confrontation this would

Taphonomy in Human Evolution, Fig. 5 The most prominent and widely publicized marks from the DIK-55 site of the Afar region of Ethiopia, dating to ~3.4 million years ago. Photo credit: Curtis Marean

have engendered with large carnivores over the same resources – began much earlier in our lineage than previously thought. Indeed, it would have meant that our relatively small-brained australopith ancestors represented by fossils such as **Lucy** or the **Dikika baby** were already entering into novel subsistence niches and leaving an early archaeological record as they did so.

However, researchers such as Domínguez-Rodrigo et al. (2010) questioned the identification of the marks as being produced by stone-wielding hominins. Instead, they proposed that they are mimics of butchery marks and that they have been produced through natural means, such as trampling. A subsequent study by Thompson et al. (2015) found that the marks on the DIK-55 fossils were outliers in terms of size and shape compared to a large sample of other marks on fossils from the same landscape. Together with the discovery of early stone tools from the Lomekwi-3 site in Kenya dating to 3.3 million years ago, the possibility of these marks being caused by trampling seems increasingly less likely. Although the debate continues, several important new developments have directly stemmed from the controversy.

During debates in the 1980s and 1990s, the issue of how to diagnose bone surface modification was tackled through actualistic research, blind tests, and the use of advanced methods such as scanning electron microscopy. However, there is a growing awareness in taphonomy that the expert knowledge-based approach to identifying surface marks is inconsistent and subject to specific and unknowable biases (e.g., the background of the expert, their experience, and the reference collections they have studied). It is also problematic that surface modifications are given a firm "yes or no" identification as a given type of mark, when in reality marks may fall along a continuum of likelihood of the agency that caused them. One solution is to employ a statistical Bayesian model to assign a probability that a given mark was caused by any of several possible agents (Harris et al. 2017). Such a model is trained on a large sample of marks caused by forces such as butchery, trampling, carnivore gnawing, and crocodile activity, and then a fossil mark of unknown origin is fed into the model – thus removing human decision-making largely from the process of identification. The output is probabilistic, assigning a degree of certainty – rather than a simple yes/no answer – that the mark was caused by each of the agents encompassed within the model. Other new approaches involve the use of 3D scanning to further remove the human element from analysis (Pante et al. 2017).

International Perspectives

Debates about early hominin subsistence – and the methodological problems that have been revealed through these debates – illustrate how taphonomy in human evolution is an ever-growing yet still relatively nascent field of study. What is also clear is that although taphonomy is a widely employed tool in zooarchaeology, only a handful of intellectual lineages have weighed substantively in on the problems of how it is applied to the human evolutionary record. Researchers from the United States and Spain working at a limited number of sites in Africa have dominated this work, apparently going through cycles of broad agreement and fierce disagreement regarding the interpretation of early zooarchaeological assemblages. It is potentially problematic that most areas of taphonomy outside of the human evolutionary sphere have not been host to such extensive controversies, because it suggests that there is less critical

inquiry about the impact of taphonomic method on zooarchaeological interpretation. These debates have fundamentally shaped Africanist taphonomy, whereas other traditions have followed different trajectories and methodological emphases. However, the problems highlighted in African contexts are not unique to Africa, nor even to early assemblages. Freshly reported controversial sites such as a purported mastodon butchery location in North America dating to >130,000 years ago, or a claimed 2.4-million-year-old butchery site in India, would also benefit from cross-fertilization of the Africanist research tradition. In spite of the association of Africa with most events in human evolution, the field of taphonomy has much to gain from a larger global conversation about equifinality and best practice in the interpretation of bone surface marks, skeletal element abundances, and other taphonomic indicators.

Future Directions

Debates in taphonomy provide valuable insight and historical perspective into how changing views of human ancestors have shifted along with the prevailing research climate. With respect to early modern human behavior, new discoveries have been accompanied by a new willingness by archaeologists to accept that members of our species *Homo sapiens* engaged in complex behaviors far earlier than the recent Stone Ages. Deeper in time, researchers have alternatively used the Olduvai sites as evidence for home bases analogous to hunter-gatherer camps, opportunistic scavenging sites, or something in between. Fresh interpretations of old evidence have also brought older ideas back to the forefront, and in many cases (as at Zinj) more than five different researchers have used the same fossil datasets to argue for completely contradictory interpretations of past hominin behavior. They have accompanied each interpretation with inbuilt assumptions about the skills our ancestors had, their social relationships, and their role in the broader ecosystem. The unavoidable truth is that new sites are needed and that this requires field research in unexplored areas. In some cases, new sites are already yielding new and unexpected results, such as the discovery of an entirely new kind of hominin at Rising Star Cave in South Africa that lived at the same time as modern humans (Dirks et al. 2017). Taphonomic work will be crucial for understanding how those remains came to rest in the cave complex and if there is any evidence of intentional deposition of the dead.

New fieldwork must also take on a different character. It has long been assumed that archaeological field methods (detailed survey and systematic collection across a landscape) would not be useful in deposits that predate the origin of our genus *Homo*, which until recently was considered to be the first stone tool maker. However, with the possibility that other (and earlier) hominins may have created an archaeological record – possibly through subtle indicators such as marks on fossils – comes the need for such systematic work. Collection of fossils can no longer be restricted only to those that are likely to be taxonomically informative, such as complete long bones. Instead, many decades of actualistic research have shown that long bone shaft fragments may be key to detecting past hominin interactions with bones. Future fieldwork in Pliocene deposits is likely, therefore, to include more archaeologists (rather than mainly paleontologists) and be burdened less by assumptions about what is and is not possible to be found.

There is also much useful actualistic research remaining to be done. Most work to date only addresses one or a handful of the potential processes that can impact a bone from the time an organism dies until the time the fossil is studied. How longer-term processes such as fossilization can impact patterns of marks, fragmentation, and skeletal part representation remain very poorly understood, in part because they are so difficult to replicate in modern settings. Overprinting of processes may create unique traces that have not yet been replicated or may not be possible to replicate with great fidelity. The full range of variability in marks created by extinct organisms in the past (such as saber-toothed cats or large extinct crocodiles) is also under-studied and should be approached through a combination of

mechanical modeling and studies of fossil collections. Future work will result in clear tests of the evidence for australopith meat-eating through new theoretical frameworks, empirical data, and analytical and field methods. Ultimately, it matters less what caused the marks on the DIK-55 bones than the fact that long-held paradigms about early hominin ecology are shifting. Taphonomy in human evolution is already seeing the start of such a surge of new information, and its adherents will soon be confronted with the need to establish standard protocols about how we can know what we think we know – along with an honest assessment of what is perhaps in the end unknowable.

Taphonomy of Plant Micro-remains in Environmental Archaeology

Alison Crowther
School of Social Science, The University of Queensland, St Lucia, Brisbane, QLD, Australia
Department of Archaeology, Max Planck Institute for the Science of Human History, Jena, Germany

Introduction

The analysis of plant micro-remains, such as starch granules, phytoliths, and pollen, is now well established among the suite of analytical tools employed by environmental archaeologists to document past human-plant interactions. These micro-remains can occur as residues on pots and other plant-processing tools, in sediments from agricultural features or on-site activity areas, or trapped in dental calculus, food remains, coprolites, and stomach contents. Accurate archaeological reconstructions rely on a firm understanding of the taphonomic processes affecting plant microfossil assemblages at all stages of their depositional history. Broadly speaking, there have been two main areas of archaeological enquiry in this direction. The first examines how plant micro-remains are deposited in the archaeological record through cultural and natural processes, and the second examines how they survive archaeological time periods in their burial environment, including the possibility of post-depositional movement. Common to both is the need to understand the potential biases in the deposition, preservation, and recovery of micro-

remains, depending on variables such as the plant part from which they originate (e.g., seeds, tubers, leaves, etc.), the method by which they are processed, altered, or transformed prior to deposition, the nature of the burial context and local microenvironmental conditions, and the post-excavation methods employed during analysis.

Definition

Taphonomy was originally defined by the palaeontologist, Efremov (1940), as "the study of the transition (in all its details) of animal remains from the biosphere into the lithosphere." This definition was later broadened to include plant remains (Lyman 2010). As applied within archaeology, it is generally taken to include all natural and cultural formation processes occurring both before and after burial. Following Madella and Lancelotti (2011), taphonomy is taken here to refer to all transformations occurring to plant micro-remains before deposition, during burial, and after excavation that may bias the recovery and interpretation of micro-botanical assemblages.

Plant micro-remains, which are sometimes referred to as microfossils, comprise a range of microscopic plant components that accumulate in archaeological deposits through daily human actions, such as cultivation, food- or crop processing, storage, consumption, discard, and craft activities. Owing to their small size, they usually require the use of a microscope for identification, which is based on morphological variations between plant families, genera, and species. The most common plant micro-remains analyzed in environmental archaeological settings are phytoliths, starch grains, and pollen, as well as a variety of non-pollen palynomorphs (e.g., microscopic remains of algae, cyanobacteria, fungi, and cormophytes). Phytoliths are opaline silica deposits that form in the cells and tissues of plants. Starch granules are composed of semicrystalline, complex carbohydrates, and are produced in plant tissues for energy storage. Pollen is the male reproductive cell of a plant. A variety of other plant tissues, fibers, and crystals (e.g., calcium oxalates) are also frequently analyzed, particularly when preserved as micro-residues on plant processing tools or in water-logged deposits. However, these tend to have less diagnostic potential and have also been subject to less intensive taphonomic investigation (cf. Crowther 2009a, b). This entry focuses on starch and phytoliths, which are now commonly analyzed in tandem and offer a useful contrast between how taphonomic processes differentially affect remains of organic and biomineral composition. Pollen is also discussed in some examples.

Historical Background

Interest in plant micro-remain taphonomy generally developed out of the processual movement of the 1960s and 1970s. At this time, archaeologists began to recognize the importance of understanding site formation processes for making accurate archaeological reconstructions, including the potential for multiple stages of burial, exposure, and transportation of remains. They also began adopting a more rigorous scientific approach to the investigation of these processes, often within the framework of middle-range theory.

In early studies of plant micro-remains on stone tools, the main taphonomic questions concerned whether residues were cultural or natural in origin. Experiments addressing the persistence of plant micro-remains over long timeframes, particularly starch granules, began to appear in the late 1990s (e.g., Barton et al. 1998; Lu 2003). Recent studies have begun exploring more systematically the effects of food and crop processing on micro-botanical assemblages through experimental and ethno-archaeological programs (e.g., Harvey and Fuller 2005; Henry et al. 2009; Crowther 2012). The emphasis of current research continues in this direction, stressing the integration of experimental studies, ethno-archaeological data, and archaeological findings, in order to provide greater insights into the taphonomic biases that are likely to affect micro-botanical preservation. With the development of more sophisticated molecular

techniques, researchers are also starting to investigate the molecular taphonomy of plant micro-remains to better understand long-term preservation, particularly of organic plant components such as starch (e.g., Collins and Copeland 2011).

Key Issues/Current Debates

A range of taphonomic processes can affect archaeological plant micro-remains at all stages of deposition, burial, and post-excavation. These factors can be broadly grouped into physical, chemical, or biological in origin. Because different types of micro-remains have different morphological and molecular structures and chemical compositions, they also have different susceptibilities to taphonomic agents. As the following discussion demonstrates, the variables influencing these processes can also interact with one another in complex ways, making the preservation of micro-remains over archaeological time periods difficult to predict.

Pre-burial Depositional Processes

Both human and natural processes play an active role in the formation of the micro-botanical record. The first question that archaeologists might ask, therefore, is whether plant micro-remains were deposited naturally or through cultural activities. The most direct nonhuman trajectory for micro-remains such as starch and phytoliths to enter the archaeological record involves the natural death and decay of plants leading to the localized deposition of micro-remains in the soil. However, they can also be subject to wind-, fire-, and water-borne deposition (Piperno 2006: 21). The main dispersal mechanisms for pollen is wind, with transportation distances ranging widely between taxa. Animal vectors also contribute to ancient plant micro-remain assemblages. While animals such as insects, birds, bats, and mammals are widely recognized as being major agents in pollination, recent studies are also drawing attention to animal dung as a natural source of pollen and phytoliths in archaeological deposits, particularly in biologically rich caves where droppings can create distinct depositional zones (e.g., Hunt and Rushworth 2005). Among the most significant of these agents are owls and raptors in temperate regions, hyaenas and other terrestrial predators and scavengers in the Old World, and bats and birds in the tropics. Domestic animal dung can also introduce micro-remains from consumed plant foods (Piperno 2006: 21). These natural depositional pathways can be complex and unpredictable, and can be influenced by a range of secondary processes such as sedimentary transportation through wash or mudflow (Madella and Lancelotti 2011). While these processes have been studied extensively by palynologists and phytolith analysts (e.g., Pearsall 2015: 190–191; Piperno 2006: 21), they have generally been given far less consideration by starch analysts. The potential for starch-containing pollen grains to be a natural vector for starch dispersal (Laurence et al. 2011) has also only recently been investigated. Airborne dispersal of micro-remains raises a number of issues for archaeologists. Not only does it further complicate differentiation between cultural and natural accumulation but it also raises the possibility of modern contamination during excavation and sampling (an issue discussed further below in relation to postdepositional movement). Mechanical stress such as attrition, rounding, or breakage may be an important indicator that phytoliths have been transported long distances by water or wind.

Targeting plant micro-residues on tools that were used for plant processing (cutting, grinding, pounding, cooking) as opposed to those accumulated in sediments can, to an extent, circumvent these issues. In these types of studies, however, the potential for micro-remains preserved in sediments to be redeposited onto tools also needs to be accounted for (discussed further below). Physical modifications to plant micro-remains arising from cultural activities such as food processing are another important indicator for differentiating anthropic from natural input.

Plant-Processing Activities

Human activities such as crop- or food processing can bias assemblage compositions, particularly

through the differential removal or deposition of micro-remains. Studies have approached this problem from two main directions. The first has been to attempt to understand how different food-processing techniques create diagnostic patterns in the micro-botanical record, which can then be used to reconstruct activities in the past. For example, Harvey and Fuller (2005) have developed models for reconstructing rice and millet processing stages based on the composition of phytolith assemblages created at different stages of processing (harvesting, threshing and winnowing, storing, parching, milling and pounding, cooking). Starch granules have been found to be particularly useful for identifying past food-processing methods based on granule modification patterns (e.g., Henry et al. 2009; Crowther 2012). For example, mechanical processing methods such as grinding and pounding cause starch granules to crack, break, and tear, and also alter their surface texture (Fig. 1). Cooking (heating in the presence of moisture) causes granules to gelatinize, by which they swell and rupture, losing their morphology and semicrystalline structure (Fig. 2). During fermentation, starch is broken down by a specific type of enzyme called amylase, which corrodes the granule's concentric growth layers either from the surface (exo-corrosion) or from the inside-out through channels digested into the center of the grain (endo-corrosion) (Fig. 3).

The second approach has been to examine how different food-processing methods can bias the survival of certain types of micro-remains over others. For example, during cooking, starch granules will undergo different degrees of gelatinization depending on the amount of accessible moisture in the cooking system (Fig. 2). As a result, granules are more likely to survive when dry cooking methods are used (e.g., toasting, baking) as opposed to wet cooking methods (e.g., boiling, steaming). Granules from relatively dry plant parts, such as seeds and nuts, will be less gelatinized than those from moisture-rich roots and tubers when whole foods are cooked (Crowther 2012). These taphonomic biases are seen as likely having an effect on the differential recovery of starches from ancient cooking pot residues, with root and tuber starches being significantly underrepresented in comparison to those from cereals and legumes in some cases (Zarrillo et al. 2008). Starch granules that have been physically modified during food processing, particularly during cooking, are also as much as 4000 times more susceptible to enzymatic degradation in the burial environment (Barton and Matthews 2006: 86). These taphonomic issues highlight the importance of integrating multiple micro- (and macro-) botanical approaches to overcoming differential biases during deposition.

Taphonomy of Plant Micro-remains in Environmental Archaeology, Fig. 1 Starch granules from (**a**) wheat and (**b**) maize showing mechanical alterations from grinding. Note the torn granules in (**a**), and the opened and enlarged central hila (growth initiation points) and roughened surfaces of the granules in (**b**)

Taphonomy of Plant Micro-remains in Environmental Archaeology, Fig. 2 Starch granules from potato (**a**–**b**) and wheat (**c**–**d**) showing unaltered (**a**, **c**) and gelatinized (**b**, **d**) forms. Note the swelling and distorted morphology of the gelatinized granules compared to the unaltered forms. The potato starch granule is more gelatinized than the wheat starches because it had access to more moisture during heating, and swelling was not physically restricted (the wheat starches were cooked in situ within the wheat grain, whereas the potato starch granules were dispersed in water then heated)

Taphonomy of Plant Micro-remains in Environmental Archaeology, Fig. 3 Triticeae-type starch granule with surface pits from enzymatic corrosion (indicated by arrows); (**a**) plane- and (**b**) cross-polarized light

Postdepositional Preservation and Decay

The questions of how plant micro-remains survive archaeological time periods after burial, how they are physically and chemically modified during this process, and whether there is the potential for differential preservation have undoubtedly dominated taphonomic discussions in recent years. Even so, for some types of micro-remains – particularly starch granules, which are organic and thus highly susceptible to degradation – these issues are still far from being fully understood (Mercader et al. 2018). Part of the difficulty in answering these questions lies in the wide range of physical, chemical, and biological variables that have the potential to influence preservation and decay. These variables can interact in complex and often unpredictable ways to either promote or inhibit microfossil degradation within the burial microenvironment. These factors include acid-base status (pH), temperature, moisture content, inorganic sediment components, plant degrading microorganisms, and physical processes that can either cause damage through mechanical attrition or inhibit degradation through the entrapment of the micro-remains in soil aggregates or mineralized deposits (e.g., dental calculus). The susceptibility of plant microfossils to degradation also varies significantly within and between types of remains, creating many challenges for environmental archaeologists attempting to reconstruct past assemblages from their present compositions.

Phytoliths are considered to be among the most durable of all plant micro-remains. Being inorganic, they do not rely on exceptional preservation conditions such as carbonization, waterlogging, or freezing to survive. They have been found to preserve in a wide range of burial environments, from heavily weathered soils in open-air sites to protected lake or cave deposits, and can endure for many hundreds of thousands and even millions of years (Piperno 2006: 21–22). They are stable in a wide pH range (3–9) but are rapidly dissolved once conditions exceed pH 9, particularly in warm and moist conditions. Evidence of chemical weathering is often visible in the form of surface pitting and etching (Fig. 4a). Phytoliths are also susceptible to mechanical damage, which can occur during transportation by wind or water, trampling or sediment compaction, and, as discussed above, during food processing such as grinding. Typical damage patterns include breakage of fine appendages and along weak points (Fig. 4b), chipping, pitting, and abrasion (Madella and Lancelotti 2011). In extreme cases, these morphological alterations can affect the accuracy of taxonomic and typological identifications. Phytoliths also begin to melt and distort at temperatures above about 1000 °C (Piperno 2006: 89). Phytolith degradation is not

Taphonomy of Plant Micro-remains in Environmental Archaeology, Fig. 4 Taphonomically altered phytoliths from the Tunel VII site, Tierra del Fuego, Argentina: (**a**) elongate smooth phytolith with surface erosion pits (indicated by arrows); (**b**) tracheid broken at one of its extremes (indicated by arrow). Photos courtesy of Débora Zurro

an even process, however, and a key issue for environmental archaeologists is to understand how phytoliths degrade differentially altering the composition and taxonomic diversity of an assemblage over time. Key variables that have been investigated include size and shape (i.e., surface area relative to volume), the degree of silicification (whether the phytolith was fully formed prior to the death of the cell), and the level of impurities incorporated in the opal structure or adsorbed to the surface, particularly aluminum, which appears to inhibit chemical dissolution (Strömberg 2004; Piperno 2006; Cabanes and Shahack-Gross 2015). Overall, these studies have suggested that larger and more fragile forms such as elongates and epidermal sheets are generally more susceptible to mechanical damage than smaller and more robust types like rondels and trapezoids. Forms with greater surface to bulk ratios are more prone to dissolution, as are those from deciduous trees (compared to grasses and conifers).

While the long-term durability of phytoliths can be readily explained as a function of their mineral composition, the survival of starch granules is not nearly as well understood and remains a highly controversial subject in micro-botanical analysis (Mercader et al. 2018). Composed of glucose polysaccharides, starch granules are susceptible to postdepositional degradation by a range of physical, chemical, and biological mechanisms. These include enzymatic hydrolysis by soil-borne microorganisms, mechanical attrition by movement or compaction of the sediment, stress fracturing from freezing or repeated cycles of wetting and drying, chemical dissolution caused by very acidic or alkaline conditions, and thermal decomposition caused by exposure to extremely high dry heat (>180 °C) or moderate heat (>40–50 °C) in the presence of moisture (Haslam 2004; Barton and Matthews 2006; Henry 2015). Despite having a seemingly low potential for long-term preservation, a growing number of archaeological studies has clearly demonstrated that starch granules can in fact preserve for very long periods – more than 100,000 years on the surface of stone tools and up to 200,000 years in mineralized dental calculus (Mercader 2009; Henry et al. 2011) – in a wide variety of contexts and depositional environments, including harsh tropical conditions. Consequently, there has been considerable discussion and debate in the literature concerning the possible preservative mechanisms of ancient starch (e.g., Haslam 2004; Barton and Matthews 2006; Barton 2009; Henry 2015) and the influence that diagenetic alterations might have on taxonomic identifications and behavioral reconstructions (e.g., Collins and Copeland 2011; Henry et al. 2011).

One of the main hypotheses for explaining archaeological starch longevity draws on the general observation that granules seem to survive best in protected microenvironments, such as embedded in pits and cracks on artifact surfaces, or encapsulated in mineralized dental calculus, in charred residues on pottery, or in soil aggregates. Such depositional contexts may physically restrict starch-degrading enzymes (amylases) from accessing granules (though this hypothesis generally lacks empirical support; see Mercader et al. 2018: 780) and could also protect them to some extent from fluctuations in soil moisture, temperature, and pH (Haslam 2004; Barton and Matthews 2006). Conditions in the burial microenvironment can also have an effect on bioactivity. Factors likely to slow biological decay include low moisture content, high or low pH (amylases have a pH-optimum around neutral), low oxygen, low temperature (amylases are optimal around 35–40 °C and deactivate below about 5 °C and above 50 °C), and the presence of heavy metals (e.g., copper, lead, manganese), clays, tannic acids, and soil aggregates (Haslam 2004; Barton and Matthews 2006; Langejans 2010; Mercader et al. 2018). Peri-mineralization or fossilization of starch granules may play a role in long-term preservation (Mercader et al. 2018: 782). However, some studies observe that ancient granules remain reactive to starch-specific stains (iodine potassium-iodide) and enzymes (Barton and Matthews 2006; Hardy et al. 2009), suggesting mineralization is either incomplete or not relevant to all cases. Molecular changes that might promote preservation such as polysaccharide cross-linking have been proposed but not yet tested (Barton and Matthews 2006).

Burial experiments have also shown the importance of protected depositional settings in shielding starch from degradation and have highlighted the highly variable nature of decay processes depending on local burial microenvironment (Lu 2003; Barton 2009; Langejans 2010). For example, a study by Barton (2009) showed that even when left on the ground surface and exposed to the elements, starch residues on stone tools survive better than when buried in loose, aerated, and biologically active A-horizon soil, where conditions are conducive to rapid microbial decay. Barton (2009; see also Langejans 2010) proposed that the formation and rapid desiccation of an organic residue complex (composed not only of starches but also of other plant matter including hydrophobic lipids) on tool surfaces during plant processing could further protect starches from microbial degradation. Experimental studies have also shown that decay rates can slow down over long depositional periods, particularly in stable environments where organic micro-remains and degrading mechanisms are more likely to reach equilibrium (Langejans 2010).

Like phytoliths, ancient starch assemblages can also be biased by differential degradation based on intrinsic, species-specific properties such as grain size, shape, and composition (amylose and amylopectin ratio). In general, granules with smaller diameters (and thus higher relative surface areas), lower amylose contents, greater numbers of surface pores, and physical modifications or damage (particularly by gelatinization) are more susceptible to biotic degradation (Haslam 2004). Smaller granules, on the other hand, are more likely to be protected from mechanical damage than larger grains. Overall, however, differential decay and preservation processes in starches are still not well understood, and such biases are still rarely factored into archaeological interpretations. Long-term diagenetic effects on starch morphology and structure are also significantly under-researched (Mercader et al. 2018). This issue was highlighted during a recent debate where the gelatinized appearance of starch granules recovered from Neanderthal dental calculus was interpreted on the one hand as evidence of cooking (Henry et al. 2011) and on the other as the result of taphonomic alterations (Collins and Copeland 2011). As Collins and Copeland (2011) argue, much more rigorous biomolecular studies of starch diagenesis are needed to understand not only how starch molecules survive but also how they are altered by chemical and hydrothermal processes through deep time.

Like starch, pollen granules are organic and thus vulnerable to a similar range of postdepositional decay mechanisms. However, they are generally considered more resilient than starch owing to the presence of sporopollenin in their tough outer walls (exine), which affords them resistance to chemical and bacterial attack. Pollen is nonetheless still prone to microbial decay, as well as oxidative damage in conditions of high redox potential (Eh), chemical corrosion in neutral or alkaline pH, and physical weathering from mechanical forces (e.g., movement, compaction, wet and dry/freeze, and thaw cycles) (Pearsall 2015: 260–261). Similar protective mechanisms that inhibit microbial activity as outlined above for starch have also been cited for pollen, with waterlogged conditions being considered optimal overall. Pollen assemblages are also subject to differential preservation depending on taxonomic variation in the sporopollenin content of grains, with grass pollen being noted among those that tend to preserve poorly (Strömberg 2004).

Overall, a stable and physically protective microenvironment in which fluctuations in temperature and moisture are minimized and movement is restricted will be favorable for the longevity of all types of plant micro-remains.

Postdepositional Movement

The question of whether plant micro-remains are in their original (primary) depositional context, or if they represent a younger (or older) contaminant that has moved into that context, is critical to archaeological reconstructions. The main mechanisms causing postdepositional movement are water percolation and bioturbation by animals (worms, insects, reptiles, mammals) and plants roots. Owing to their small size, micro-remains are often considered to have high potential for moving between stratigraphic contexts, including

from the depositional sediment onto the surface of a buried artifact. Experiments have shown that there is a great deal of variation in the extent to which micro-remains move, depending on the characteristics of the archaeological matrix (e.g., pore size, degree of compaction), the size and shape of the microfossil, and the intensity of water flow (Hart and Humphries 2003). The degree of bioturbation tends to be affected by the aerobicity of the sediments, with more aerobic sediments supporting greater bioactivity.

Experimental studies aimed at quantifying the water-borne movement of starch grains in sediment columns (Therin 1998; Haslam 2009) have shown that, even in relatively porous sands and under tropical rainfall conditions, few granules of any size move. Furthermore, while small particles (<5 μm) are more likely to move overall, large particles tend to move further once mobile, presumably because of their greater density. Some lateral and upward movement can also occur owing to capillary forces. While field and laboratory experiments with phytoliths have found similar results, showing the higher mobility of small-sized particles, as well as those with elongate shapes (aspect ratio >3), they have also highlighted the importance of soil microstructure in either facilitating or inhibiting the displacement of plant micro-remains (Fishkis et al. 2010). In particular, the presence and size of macropore channels and the intensity of aggregate formation with clay particles, organic substances, and oxides appear to play an important role. Fishkis et al. (2010) suggest that these types of natural soil conditions have not been adequately simulated in many laboratory experiments, which typically use homogenous packed-sand matrices that may in fact retard microfossil mobility. While experimental studies serve as a useful guide for understanding the influence of key variables under controlled conditions, the degree of microfossil movement is clearly dependent on a range of interacting field and sedimentary conditions, and must be assessed on a case by case basis.

Archaeologists have more commonly relied on patterns in the archaeological record to assess the likelihood of postdepositional movement, particularly by comparing the composition of micro-remain assemblages across multiple spatial and temporal contexts. For example, phytolith and starch studies in the Pacific Islands have analyzed sterile subsoils underlying archaeological layers or tephra deposits alternating with palaeosols to assess the down-washing of microfossils (Horrocks and Weisler 2006; Lentfer and Torrence 2007). In both cases, movement was found to be minimal. In their multi-proxy analysis of maize use at Late Archaic sites in Peru, Haas et al. (2013) argued that the pollen found in prehistoric contexts was unlikely to be modern contamination because grains from a recently introduced invasive genus, which were prevalent along with maize in modern control samples, were absent from the archaeological samples. Stratigraphic evidence of bioturbation such as burrows, insect channels, or worm cases, or other major disturbances such as pits or channels can also be useful in assessing the degree of mixing and can be assisted by micromorphological studies (Madella and Lancelotti 2011).

Spatial distribution patterns are also assessed during residue studies to determine if micro-remains have migrated from the surrounding sediment to the surface of an artifact. The typical approach is to compare the frequency and types of micro-remains found on the used edges of tools to those in the surrounding sediment and in other control samples (e.g., Piperno et al. 2000). For example, Barton et al. (1998) found significantly higher quantities of starch on used obsidian flakes (which was determined independently by use-wear analysis) than on unused flakes or in the surrounding sediment at sites in Papua New Guinea. "Sealed" contexts such as dental calculus or charred food crusts on ceramics are also considered to be less susceptible to contamination, although this has yet to be thoroughly tested (though see Soto et al. 2019). Charred food crusts, for one, are likely to contain an interconnecting network of micro-cracks, pores, and channels that form during charring, which may be readily penetrated by water-mobilized micro-remains in the burial environment. To address this issue, Saul et al. (2012) compared starch frequencies in charred food residues on potsherds to those occurring in soot deposits on the same sherds to

demonstrate that the starch granules had not percolated into the food crust. Detailed context-based analyses such as these provide a strong basis for assessing the stratigraphic integrity of plant micro-remains and are now considered an essential component of micro-botanical studies.

Post-excavation Processes

Increasing attention is also being paid to the taphonomic processes that affect micro-botanical remains after they have been excavated, particularly during laboratory processing and analysis. Some form of extraction is usually required to recover plant micro-remains from archaeological samples, whether they are sediments, tool residues, or dental calculus. Most techniques use either mechanical or chemical methods, which can physically transform or degrade the microfossils and in some cases selectively remove certain types from the sample such as through size separation. For example, the extraction protocol recommended by Therin and Lentfer (2006) for separating starch granules using heavy liquid flotation is designed to recover granules >5 μm in diameter. Studies using this method may therefore be biased against recovering evidence of major economic crops such as rice and taro, which produce starch granules smaller than this threshold size. Such technical limitations must be fully understood and taken into account in archaeological reconstructions. Analysts have also recognized the potential for biases to be introduced during phytolith extraction. For example, acid extraction procedures as well as mechanical crushing have been shown to cause conjoined (multicelled) phytoliths to break down into single-celled forms during laboratory processing, while dry ashing can cause them to fuse together (Jenkins 2009). Slide preparation methods are also a potential source of bias, particularly through differential size sorting (Strömberg 2007).

It is now also common for micro-botanical studies to extract multiple types of microfossils such as both starch and phytoliths from one sample (Piperno 2006). Extraction techniques therefore have to be designed and implemented carefully to avoid damaging or destroying the more fragile types, particularly starch. This includes limiting the use of heat (>35 °C), strong acids and oxidizers, and excessive mechanical processing such as grinding and sonication. Some analysts have even observed the long-term degradation of samples during storage, including damage caused to ancient starch granules by certain mounting media (e.g., Piperno 2006). These issues are particularly important given that many types of damage caused during laboratory processing can resemble modifications induced during food processing, potentially leading to the misidentification of these culinary practices in the archaeological record (cf. Collins and Copeland 2011).

International Perspectives

The analysis of archaeological plant micro-remains has been most commonly applied as an integrated methodological approach in tropical regions such as Australasia and the New World, where macro-botanical remains tend to be poorly preserved. As a result, much of our present understanding of the taphonomy of plant microfossils has also tended to focus on these regions. In recent years, however, there has been a major geographical expansion of research in areas such as South and East Asia, Europe, and Africa. Each of these regions has different environments, different food plants, and different culinary traditions that can differently affect the taphonomic pathways of plant micro-remains. Plant micro-analysts are therefore not only beginning to appreciate the full scope of archaeological conditions under which micro-remains can be deposited, altered, preserved, and recovered over various time scales, but are also increasingly conducting regionally specific experimental studies and developing taphonomic models designed to understand these processes in their local setting.

Future Directions

While much progress has been made towards understanding the taphonomy of plant micro-

remains, there are still large gaps in our knowledge, as well as major deficiencies in the way we apply this knowledge in archaeological reconstructions. Taphonomic studies of modern analogues, such as experimental or ethnoarchaeological research, in which relevant cause and effect relationships are known, are still the cornerstone of much of our current knowledge and should continue to be so in the future. An important area for further consideration is the development of long-term actualistic studies that simulate more realistically the complexities of pre- and postdepositional processes operating over archaeological time scales. Broader consideration should also be given to the noncultural vectors by which plant micro-remains can enter the archaeological record, including modern post-excavation contaminants that may enter samples inadvertently during field sampling or laboratory processing (Crowther et al. 2014; Mercader et al. 2017).

As the analysis of plant micro-remains becomes more routine in archaeological studies, so too should the recording of taphonomic factors important to the reconstruction of the human past. This includes the physical and chemical properties, and biotic composition of burial soils, and the collecting and reporting of field and laboratory control samples. Further, the reporting of negative results or cases where taphonomic constraints have precluded reliable reconstructions of past human-plant interactions should be encouraged. Such data sets are critical for developing a more robust understanding of the environmental conditions under which different micro-remains should be expected to survive or degrade, and for assessing contamination. As case studies worldwide have increasingly demonstrated, archaeological reconstructions are also much more robust in the face of taphonomic biases when multiple lines of evidence are employed. Integrated multi-proxy approaches to reconstructing human-plant interactions should therefore be adopted where possible.

One of the final frontiers in plant micro-remain taphonomic studies is the building of better understandings of their molecular taphonomy, particularly of organic remains such as starch granules. Factors affecting the long-term preservation and diagenesis of starch and other organic molecules are still only poorly understood, fueling much debate about the reliability of archaeological identifications and interpretations. In addition to intrinsic molecular alterations, the potential for organic plant remains to form molecular bonds or cross-links with other components in the soil (e.g., clays, hydroxides, oxides, and humic substances) or micro-residues on tool surfaces (e.g., hydrophobic lipids) also requires systematic investigation (Barton 2009; Barton and Matthews 2006: 85; Mercader et al. 2018). The ongoing recognition and investigation of taphonomic processes such as these will ensure confident and reliable reconstructions of past relationships between people, plants, and the environment from archaeological plant micro-remains.

Taphonomy, Regional

Luis Alberto Borrero
CONICET-IMHICIHU, Buenos Aires, Argentina

Introduction

Taphonomy is a discipline common to many fields, like paleontology, geology, paleoecology, or archaeology. Its basic goal is to understand the transition of organic materials, for example, bones or soft tissues, from the biosphere to the lithosphere (Lyman 1994). Taphonomic information is routinely used by archaeologists to assess the quality of archaeological data, to evaluate the loss of cultural and ecological information, to pursue paleobiological questions, and sometimes also to acquire paleoecological information (Gifford 1981; Behrensmeyer 1993; Lyman 1994; Marean 1995). In other words, the conditions which are adequate for the formation of fossils are a central concern of taphonomy. Archaeological applications are usually focused on the preservation of bones, but they also cover cases involving transformations of lithic tools, pottery, or other kinds of materials. In most cases, local scales of analysis are used – usually, the site – and indeed those scales are adequate to perform most of these tasks. The literature is full of successful examples of application of taphonomic analysis at a local scale (Pickering et al. 2007; Stuart and Larkin 2010). However, the fact that the scale at which most archaeological problems are usually stated is regional is a valid reason to also advocate for a regional scale of taphonomic analysis (Borrero 1988).

Definition

The basic goal of regional taphonomy is to understand the dynamics of environments at large spatial scales, particularly the processes responsible of bone accumulations. An accumulation of bones is usually defined as any surface or stratigraphy

occurrence of vertebrate remains of more than one individual in a well-circumscribed area, around 100 m^2 (Behrensmeyer 1991: 293), and it is the result of a variety of processes. The regional distribution of bone accumulations and its causes constitutes the central subject of the analysis (Haynes 1982; Behrensmeyer 1983; Borrero 1988). These bone accumulations may be the result of the activities of one or more agents, and one important task is that of separating those agents in an effort toward understanding the causes behind the different bone accumulations. Taphonomic analysis can help to separate fossil bone accumulations created by hominins, carnivores, water, or other varied agents (Haynes 1980; Behrensmeyer 1991; Gutiérrez et al. 2010). On the other hand, beyond the identification of the depositional agents, a regional taphonomy may provide an understanding of the impact of the recent natural "bone rain" on the regional archaeological record. The formation of palimpsests and other issues of contamination of archaeological and recent bone assemblages can be assessed in this way. In other words, an understanding of what bones can be used for a cultural discussion and what bones inform on modern and fossil natural processes at different loci is the expected result of a regional taphonomy.

Historical Background

Taphonomic research in Tierra del Fuego provides a substantial example of some of the properties of a regional taphonomy. This example highlights the importance of the processes of contamination of archaeological sites with modern bones and the necessity to understand the causes creating those palimpsests. The San Pablo region in the Atlantic coast of Tierra del Fuego, Argentina, is characterized by extensive Nothofagus sp. forests that alternate with peats and prairies. This region was actively used by hunter-gatherers during the Late Holocene. It is also a place regularly inhabited by guanacos (Lama guanicoe). This study showed that most of the known archaeological sites of that region dated between approximately 300 BP and present were contaminated with recently deposited guanaco bones. Longitudinal observations made along several years confirmed the vertical migration of recently deposited guanaco bones contaminated many archaeological assemblages (Borrero 1990). This problem was aggravated by the fact that the modern bones that were contaminating the archaeological assemblages were highly fragmented. Similar mixes of old and recent bones were also noted when other archaeological assemblages were studied on the island or in Patagonia. Given the fact that guanacos were also the main prey for prehistoric hunter-gatherers, the separation of archaeological and "natural" bones is generally difficult to achieve. Generally speaking, taphonomic research produced a suite of taphonomic principles – rates of weathering, ranking of bone destruction, bone selectivity by different carnivores or by running water, etc. – that can be used to separate recently deposited bones from archaeological bones (Borrero 2007). This separation is crucial to acquire a trustable list of the guanaco parts selected for human consumption. Similar problems involve other species in other places (Behrensmeyer 1991; Lyman 1994).

Key Issues/Current Debates

Knowledge about the regional distribution of the archaeological materials is important for any regionally oriented taphonomic research program (Dunnell and Dancey 1983). In other words, this is the only way to know at which places artifacts and natural bones had the potential to overlap in space and also at which places good bone preservation is to be expected. The best way to do this combines taphonomic and geoarchaeological work.

The more useful data collection strategies are those that at the same time will record both archaeological and taphonomic information. Surface bones recorded in transects or blocks (Behrensmeyer 1983) need to be classified by species, element, completeness, degree of disarticulation, abrasion stage, weathering stage, and

classes of damage (carnivores, rodents, etc.) (Lyman 1994). When possible, evidence of cause of death, age at death, presence of associated tracks, feathers or scats, and type of substrate must also be recorded. The potential for burial can be evaluated not only by using soil probes but also by analyzing the correlation between weathering stages and bone burial – usually defined as 50% or more of the element covered by sediments (Behrensmeyer 1991). Frequency information is usually transformed into densities per square meter to facilitate comparisons. The archaeology of the places that show high risk of bone contamination needs to be stratigraphically examined using test pits. In this way, by using the locally recorded fossil and taphonomic information and general taphonomic principles, the degree of bone contamination can be assessed.

Other regional approaches to taphonomy exist, some of which rely almost exclusively on naturalistic data. One example is the work of Blumenschine (1987) at Serengeti and Ngorongoro, Kenya. This particular study was oriented toward the identification of the scavenger opportunities offered by modern environments. The research goal was to use them as analogs for the Plio-Pleistocene hominin landscapes. This study was criticized for two main reasons. First, it was observed that even the best modern analogs differ significantly from the habitats of the Plio-Pleistocene in the variety and distribution of carnivores and herbivores. Second, it was suggested that places like Serengeti cannot be considered as the best analog for that period in East Africa (Tappen 2001). Anyway, this is an extreme situation in which environments separated by c. two million years or more are compared. In spite of the tremendous differences imposed by this situation, regional naturalistic observations have proved important in the evaluation of many similar situations (Haynes 1982; Behrensmeyer 1983). This is particularly true when these observations are complemented with experimental taphonomic work (Dominguez-Rodrigo 2012). An understanding of the basic processes that govern the deposition and preservation of organic remains provides ways of separating those components of the fossil record that can be attributed to human activities.

Most of the approaches that try to identify regional taphonomic signals principally work with surface records, but there are conditions under which stratigraphic approaches can be used as well. One example is the work at Olorgesailie, Kenya, where the spatial distribution of at least two different time periods was examined and compared using regional taphonomic properties (Potts et al. 1999). In the ideal case, both surface and stratigraphic samples should be employed, and it is their comparative integration that proves to be more informative.

Future Directions

Regional taphonomy is a way to study and understand potential biases affecting archaeological assemblages. It is also a useful way to acquire paleoecological information and to select the most adequate places to answer specific research questions. Effectively, an understanding of the formation of palimpsests can be used to select places with better integrity or with the capacity to inform about particular activities, like scavenging or hunting. In turn, the knowledge about the aggregational history of the deposits can be used to study paleoclimatic and palaeoenvironmental issues (Bobe et al. 2007). For these reasons, regional taphonomy is a research strategy that appears to be especially not only useful during the early phases of archaeological research but also capable of obtaining primary information. Most places in the world offer conditions for contamination of older bone assemblages with more recent bones. Regional taphonomy offers one way to respond effectively to that challenge.

Taphonomy: Definition

Soren Blau
Department of Forensic Medicine, Victorian Institute of Forensic Medicine, Monash University, Southbank, VIC, Australia

The term taphonomy (from the Greek *taphos*-τάφος meaning burial and *nomos*-νόμος meaning law) is defined as the study of the transition of plant and animal organisms after death from the biosphere (living surfaces) to the lithosphere (underground). Taphonomists study processes such as decomposition or burial that affect organisms after death and which ultimately result in animals and plants becoming part of the fossil record.

Tarlow, Sarah

Dan Hicks
Institute of Archaeology, Pitt Rivers Museum, University of Oxford, Oxford, UK

Basic Biographical Information

Sarah Tarlow is a historical archaeologist based in the United Kingdom. She received her B.A. in English Literature from Sheffield University in 1989 and her M.Phil. (1990) and Ph.D. (1995) in Archaeology from the University of Cambridge. She taught at the University of Wales, Lampeter, between 1995 and 2000, before taking up a position as lecturer in Historical Archaeology at the University of Leicester. She was appointed to senior lecturer in 2006 and was appointed to a personal chair in spring 2012.

Among many high-profile professional duties, Tarlow has been an active editorial contributor to the journal *Archaeological Dialogues* and the leading figure in the development of the teaching and research programs in Historical Archaeology at the University of Leicester.

Major Accomplishments

Tarlow's doctoral thesis, supervised by Ian Hodder, was titled *Metaphors of Death in Orkney, CE 1600–1945* and explored how early modern and modern gravestones could be studied by archaeologists as evidence of attitudes to death, and especially to the history of emotion and affect. Developed into a book-length study of *Bereavement and Commemoration* in 1999, Tarlow's Orkney research pioneered research into the archaeology of emotion, actively critiquing previous (especially Marxist) archaeological studies of funerary practices from a distinctive perspective that holds some commonalities with feminist archaeologies.

During the 2000s, Tarlow's studies of modern death came to engage more with social history: both through her account of Oliver Cromwell's head (Tarlow 2008) and her book-length study of *Ritual, Belief and the Dead in Early Modern Britain and Ireland* (Tarlow 2011). In 2011, this led to the award of a large research grant for a groundbreaking interdisciplinary project "Harnessing the Power of the Criminal Corpse" (funded by the Wellcome Trust), which brings archaeological thinking together with medical and criminal history, folklore, literature, and philosophy.

At the same time, she has contributed significantly to methodological and theoretical debates about the relationships between archaeology and history: in her pioneering edited volume *The Familiar Past?* (with Susie West 1999), in her groundbreaking studies of utopian communities, and in her book-length account of the archaeology of improvement in the eighteenth and nineteenth centuries (Tarlow 2007). Tarlow also played an active role in the early development of the CHAT conference group, hosting the second (2004) meeting at the University of Leicester.

Taro: Origins and Development

Peter J. Matthews[1] and Dzu V. Nguyen[2]
[1]National Museum of Ethnology, Osaka, Japan
[2]Institute of Ecology and Biological Resources and Graduate University of Science and Technology (Vietnam Academy of Science and Technology), Hanoi, Vietnam

Basic Species Information

Taro (less commonly: *cocoyam, dasheen, eddoe*) (English), *kolokasi* (Greek), *qolqas* (Arabic), *kachu* (Bengalese), *arvi* (Hindi), *pein-u* (Burmese), *yu* (Chinese), *satoimo* (Japanese), *khoai nuoc* (Vietnamese), *gabi* (Tagalog), *kaladi* (Malay), *talas* (Palawan, Bahasa), *taro* (Maori, Samoan), *ma* (Papua New Guinea), *gwaza* (Hausa), *iso koko* (Yoruba), *ede epi* (Igbo), and *mayugwa* (Zanzibar). The genus *Colocasia* (L.) contains at least nine and perhaps many more distinct species, all of which are found in humid to semiaquatic habitats in Southeast Asia to Southern China. They are soft acrid herbs, often 0.5–2 m tall, leaves large, heart-shaped, with blades supported on long centrally inserted petioles (hence peltate) above an erect or underground corm. Male and female flowers appear on the same inflorescence (spadix with spathe, raised on a peduncle). After pollination by insects, numerous berries with many small seeds are produced. Some species, including taro (*C. esculenta*, Figs. 1 and 2), display waxy, non-shining leaves that repel water (wax is on micro-hairs that reduce reflection), while others display non-waxy, shiny, wettable leaves (e.g., *C. lihengiae*, Fig. 3). On taro, two to several fruiting heads may appear in sequence in one season from a single axil. Vegetative propagation of taro is by side-corms with many buds (many or most cultivars) or by long stolons with many nodes (some cultivars and most wild forms).

Taxonomy and Geographical Distribution

Taro was first described by Linnaeus in 1753 based on material derived from the Mediterranean region, where it has been cultivated since antiquity. He put the species in genus *Arum* under the name *Arum esculentum* L. In 1832, Schott transferred taro from *Arum* to a new genus, *Colocasia* Schott, based on the type species *Colocasia antiquorum* Schott, a name later understood as a synonym for *C. esculenta* (L.) Schott. Many different names have existed for the same plant, including *Caladium esculentum* (L.) Vent. 1801, *Colocasia esculenta* var. *aquatilis* Hassk. 1840, *C. antiquorum* var. *aquatilis* (Hassk.) Krause 1920, and *C. esculenta* var. *antiquorum* (Schott) Hubb. and Rehder 1932. Early taxonomists erected many species of *Colocasia* based on collections of wild plants and diverse cultivated forms of what is now called taro (*C. esculenta*). Recent work in mountainous regions of Southeast Asia has led to the discovery and description of further wild species. Consensus is lacking on the full number of distinct species; nine are noted here and more certainly exist:

1. *Colocasia esculenta* (L.) Schott 1832, highly polymorphic (Plucknett 1983) with diverse wild-type and domesticated forms; cultivated in most tropical to warm-temperate regions of the world; possibly evolved in low mountains of Southeast Asia (vicinity of other wild species in mountains), now distributed in natural and disturbed habitats in subtropical to tropical regions from India to China, Australia, and Melanesia (the likely natural range, Matthews et al. 2017) and notably absent from Taiwan as a wild plant
2. *C. formosana* Hayata 1919, abundant and widespread in Taiwan; also present in Luzon; forms a morphologically homogeneous wild population and is not known in domesticated form; morphologically distinct, but minimally so, from wild *C. esculenta* (Matthews et al. 2015).
3. *C. fallax*, Schott 1859, wild in Himalaya
4. *C. affinis* Schott 1859, wild in mainland Southeast Asia, lower altitudes

5. *C. lihengiae* Long and Liu 2001 wild in mountains, northern Vietnam to Yunnan, China, and Northeast India
6. *C. menglaensis* Yin, Li, and Xu 2004, wild in mountains, northern Vietnam to Yunnan, China
7. *C. yunnanensis* Long and Cai 2006, wild in mountains, northern Vietnam to Yunnan, China
8. *C. oresbia* Hay 1996, wild on Mt. Kinabalu, Borneo.
9. *C. gigantea* (Blume) J. D. Hook. 1893, a leaf vegetable (petiole only) in Southeast to East Asia and especially popular in Vietnam; wild in karst landscapes of mainland Southeast Asia; a taxonomic and genetic outlier, distant from other *Colocasia* species

Major Domestication Traits

Rumphius (seventeenth century) may have been the first author to describe with words and illustration a natural wild form of taro (*Caladium aquatile;* syn. *C. esculenta* var. *aquatilis;* cf. Matthews 1991) in Ambon, eastern Indonesia; he saw wild taro growing along rivers, and it was used as fodder for pigs, a usage that is widespread today in Southeast Asia. Wild taro is very acrid, like most Araceae, and is widely known as a famine food that requires special care in the selection and preparation of parts eaten (corms, leaves, stolons). Major domestication traits are:

1. Reduction in acridity of raw tissue or an increase in the susceptibility of the acrid factor (an enzyme) to heat (cooking) or both.
2. Increase in the bulk of the starchy corms, with diverse associated changes in flavor and texture.
3. Distinctive green-white, purple-red, and yellow-orange colors in leaves, stolons, corms, and inflorescences; color variation aids cultivar identification and has aesthetic appeal in gardens and on plate.
4. Cold adaptation (many small side-corms) and day-length sensitivity in northern temperate cultivars.

Acridity helps protect against herbivores, reducing costs for cultivation and storage but increasing costs for processing and consumption. In some cultivars the reduction favors consumption of starchy corms and green vegetable parts (leaves, stolons); in others it may favor corms or green parts but not both. According to cultivar, the corms, side-corms, or leaves (blade or petiole) are main parts eaten; the stolons and spathes of some cultivars are also eaten. Throughout Southeast Asia, commensal wild taro populations with relatively low acridity are harvested as a green vegetable food and as a fodder for pig, making taro perhaps the most abundant green vegetable in the region.

Timing and Tracking Domestication

Cultivars in Eurasia are very ancient since taro is mentioned in ancient texts that date back to around 2000 years ago in both China and the eastern Mediterranean (Matthews 2006). Northern, temperate-adapted cultivars of taro may have originated in the northern margins of the natural range, in eastern Himalaya, where taro could breed, where triploids often appeared, and where farmers could select traits favorable to winter storage, spring propagation, and summer cultivation. The earliest association of taro with human settlement, from 10,000 years ago, has been found at Kuk Swamp in Papua New Guinea (Golson et al. 2017). In Papua New Guinea, taro used at early dates could have been a natural wild form or could have been undergoing domestication in response to changes in landscape management, cultivation methods, cooking methods, and food preferences.

Genetic studies have shown that taro cultivars are very diverse and form a number of distinct gene pools; the great diversity within diploid and triploid cultivars ($2n = 28$, $2n = 42$) indicates domestication many times. Wild populations have not been studied in enough detail, or in enough places, to identify source regions and routes of movement. Since cultivars are carefully maintained as clones, some may be hundreds if not thousands of years old. Clones identified by the analysis of multi-locus genotypes have spread in many different directions, over vast distances,

with trade and human migration (Chair et al. 2016). The antiquity of taro in Africa is much debated. Wild populations are not known there, and the crop was possibly introduced from multiple directions at different times: overland from West Asia, via the Indian Ocean from Southeast Asia, and via the Mediterranean Sea to North Africa and the Iberian Peninsula. Taro first reached the Caribbean and Central America as a food of slaves carried from West Africa.

Tavares da Silva, Carlos

Carlos Tavares da Silva
Centro de Estudos Arqueológicos do MAEDS, Setúbal, Portugal

Basic Biographical Information

Carlos Tavares da Silva (Fig. 1) was born in Portugal in 1944. He obtained his academic qualifications in geology (1967) and biology (1975) from the Universidade de Lisboa. Between 1967 and 1974, Carlos Tavares da Silva was an archaeological adviser of the Educational Ministry (Junta Nacional de Educação) in the municipalities of Setúbal and Palmela. He was an archaeologist in Gabinete da Área de Sines, from 1972 to 1974, and he was Director of the

Tavares da Silva, Carlos, Fig. 1 Carlos Tavares da Silva (Castro de Chibanes 2012)

Archaeological Service of Gabinete da Área de Sines, from 1974 to 1988 (Tavares da Silva and Soares 1981), and he coordinated the archaeological unit of the Natural Park of Sudoeste Alentejano e Costa Vicentina between 1988 and 2000. He has been Director of the Archaeological Center of the Museum of Archaeology and Ethnography in the District of Setúbal since 1974 and co-director of the archaeological review, *Setúbal Arqueológica*, since 1974. He lectures in prehistory at the Universidade de Lisboa.

Carlos Tavares da Silva had been a member of the Scientific Committee of the Portuguese Institute for Archaeology and Cultural Heritage and of the International Union of Pre- and Protohistoric Commission on Neolithic civilizations of the Mediterranean and Europe. He is also a member of the Academia da História in Portugal and researcher of the Archaeological Center of the Universidade de Lisboa. He is the President of the Scientific Committee of the archaeological site of Tróia. He is the author and coauthor of some two hundred publications. In 2004 he was awarded the Gulbenkian Archaeological Award in recognition of his services to archaeology in Portugal.

Major Accomplishments

Carlos Tavares da Silva has directed and co-directed more than 100 archaeological excavations based on research projects and rescue programs. From 1997 to 2002, he worked on the largest archaeological project of Southern Portugal, in Alqueva, (dam of the Guadiana River) and also worked on the preceding archaeological and cultural heritage survey to evaluate the environmental impact of the dam's construction, with Joaquina Soares and José Manuel Mascarenhas.

Carlos Tavares da Silva has played an important role in the development of Portuguese urban and rescue archaeology. With Joaquina Soares, he convened the first national congress on this matter "I Encontro Nacional de Arqueologia Urbana" at Setúbal in 1985. Carlos Tavares da Silva's main contributions in the field of archaeology research are (I) formulation of the first periodization model for the Chalcolithic of Portuguese Estremadura (Tavares da Silva and Soares 1986); (II) identification of the first Chalcolithic fortifications from the III millennium cal BC in Southern Portugal, with Joaquina Soares (Ferreira da Silva et al. 1993); (III) Neolithization process in the Southwest Portuguese Coast, with Joaquina Soares (Tavares da Silva and Soares 2006); (IV) discovery and study of the settlement strategy of the Middle Bronze Age of SW Iberia (Cultura do Bronze do Sudoeste), with Joaquina Soares; (V) identification and excavation of the first Phoenician factory (Abul, in the Sado estuary) currently known in the Atlantic façade of Iberian Peninsula, with Francoise Mayet (Mayet and Tavares da Silva 2000); (VI) the urban archaeology of Setúbal; and (VII) salted fish and fish sauce industry in the Roman Period on the Southwest Portuguese Coast (Tavares da Silva and Soares 1993; Mayet and Tavares da Silva 1998, 2002).

Taylor, R. E. (Erv)

Robert Sternberg
Department of Earth and Environment,
Franklin & Marshall College, Lancaster, PA, USA

Basic Biographical Information

R. E. (Erv) Taylor (1938–) is an American archaeologist best known for his work in radiocarbon dating (^{14}C). He received his Ph.D. in anthropology at the University of California, Los Angeles (UCLA), in 1970 with an emphasis on archaeology and archaeological sciences/archaeometry. His doctoral research, under the direction of C. W. Meighan, was undertaken in the laboratory of Nobel laureate Willard F. Libby. From 1972 to 1973, he was an NSF postdoctoral fellow in chemistry at UCLA working with Daniel Kivelson.

From 1969 to 2005, he rose to professor in the Department of Anthropology at the University of California, Riverside (UCR), and has been professor emeritus since 2005. He served as chairperson of that department from 1993 to 2000. He was director of the radiocarbon laboratory at UCR from 1973 to 2003. Since 2003, he has been a Visiting Professor at the Cotsen Institute of Archaeology, UCLA, and, since 2004, has also been a visiting scientist at the Keck Accelerator Mass Spectrometer Laboratory, University of California, Irvine.

Major Accomplishments

Taylor's research has focused on examining the application of dating and analytical techniques in archaeology, with particular emphasis on radiocarbon. He is recognized for his work involving the ^{14}C dating of bone, particularly human bone samples associated or thought to be associated with the earliest human populations in the New World.

In the early part of his career, Taylor published a series of papers focused on the evaluation of ^{14}C data from various sites in West Mexico. In

connection with these studies, he published some of the first papers concerned with defining marine reservoir effects in the ^{14}C dating of shell from the Pacific coasts of North, Central, and South America and the first large suite of ^{14}C dates on organics extracted from ceramics.

In the 1980s and extending into the early 1990s, Taylor was involved in pioneering applications of the use of accelerator mass spectrometry (AMS) technology to ^{14}C dating of archaeological materials, in association with the then newly established AMS laboratory at the University of Arizona. Later, he was instrumental in developing support for establishing the Center for Accelerator Mass Spectrometry for the University of California at the Lawrence Livermore National Laboratory. More recently, he has collaborated with scientists at the W. M. Keck Carbon Cycle Accelerator Mass Spectrometry Laboratory, Department of Earth System Science, University of California, Irvine.

Taylor initiated studies with a number of collaborators resulting in major downward revisions in the Pleistocene ages assigned to a series of California Paleoindian skeletons, particularly Sunnyvale, Yuha, Los Angeles, and Haverty. The UCR laboratory was also responsible for ^{14}C dates on the Calaveras Skull, the "Piltdown" of the New World (Taylor et al. 1992a). His laboratory obtained the first ^{14}C age determinations on the Kennewick skeleton (Taylor et al. 1998). He has also been involved in continuing studies focused on the accuracy of ^{14}C dates from the site of Monte Verde in Chile and possible regional offsets in ^{14}C calibration data for the mid-1st millennium BCE (Taylor et al. 1999).

In the 1970s, Taylor was involved in early studies in obsidian sourcing and hydration dating and edited the first volume addressing archaeological and geochemical issues involving obsidian (Taylor 1976).

Taylor has authored over 100 journal articles in a wide range of scholarly journals including *Science*, *Nature*, *American Antiquity*, *Antiquity*, *Historical Archaeology*, *World Archaeology*, and *Radiocarbon*. He is the author/editor of several significant books: *Chronologies in New World Archaeology* (Taylor and Meighan 1978), *Radiocarbon Dating: An Archaeological Perspective* (Taylor and Bar-Yosef 2014), *Radiocarbon After Four Decades: An Interdisciplinary Perspective* (Taylor et al. 1992b), and *Chronometric Dating in Archaeology* (Taylor and Aitken 1997). He also has written on the history of the development of ^{14}C dating with particular attention to its early application in archaeology (Taylor 1985, 2000).

Taylor's career accomplishments were recognized with the awarding of the 2004 Fryxell Award for Interdisciplinary Research, from the Society for American Archaeology, of which he is a longtime member. He is a fellow of the American Association for the Advancement of Science and the American Anthropological Association. He was a cofounder of the Society for Archaeological Sciences, as well as its first president (1980–1981) and general secretary for 20 years (1982–2002).

Techniques of Paleolithic Art

Carole Fritz
CNRS, Université de Toulouse le Mirail,
TRACES, CREAP Cartailhac, Toulouse, France

Brief Definition of the Topic

Techniques used by Upper Paleolithic groups to produce their graphic works of art provide almost inexhaustible sources on "ways of doing." They also enable us to reflect on the levels of practice of "artists," on the internal organization of societies, and on the implication of the individuals in the procurement of pigments, tools, and mediums.

In studying the techniques of Paleolithic artists, we seek to identify the set of processes of formal construction from the level of a single trace, to their combination into the form of a drawing all the way to the use of the graphic space whether it be on a restricted medium like an object or on a wall.

The study of techniques allows for the understanding of the artists' gestures and the mediums used in the different graphic works.

The mediums of prehistoric representations are multiple and varied from objects of portable art (including bone, stone tablet, ivory, antler) to cave walls, shelters under rock, and rocky blocks in the open air. It is possible to distinguish two main categories of techniques employed: those that add material during the course of the work and those that proceed by removing matter.

In the first category we find the use of pigment for drawing or painting. The coloring is deposited on the medium (bone, rock, or others). The state of the coloring material allows us to distinguish a drawing from a painting. A painting requires a liquid pigment which is applied with a paintbrush, a brush, with the tips of the fingers, or even blown with the mouth, while drawings require a compact pigment, prepared in the form of chalk, pencil, or pastel.

The second category of techniques of Paleolithic art is illustrated by the removal of matter such as engraving, sculpture, and some types of modeling.

These general principles are applicable to all forms of prehistoric art. We see them being implemented on the first decorated representations, for example, the drawings and paintings on the Chauvet-Pont-d'Arc Cave – at 36,000 cal BP.

Upon this theoretical basis, Paleolithic techniques seem relatively simple. It is important to understand as a follow-up how the "artists" combine their gestures and whether the results obtained seem to conform to the goals that we imagine they had set for themselves.

Generally, the fundamental actions of engraving are relatively easy to master if we take into consideration some physical constraints associated with the support (bone, stone, antler) and the tool (flint, finger, stick). Once the bases are acquired, we can evaluate the quality of the designers according to two criteria: the mastery of the drawing and the technical skill. All the know-how of the Paleolithic artist resides in the acquisition of these two foundations.

The most beautiful examples of drawings in the Chauvet Cave perfectly illustrate this double mastery. Admittedly, one should not underestimate the creative imagination of the individual and its capacity for invention or for breaking the rules. Nevertheless, the expertise and graphic innovations remain in the large majority of cases subject to the social codes that govern the artistic

production of this cultural group, and the control of society over the individual is highlighted throughout the duration of the Upper Paleolithic.

From the appearance of the first graphic manifestations, all techniques (engravings, sculpture, drawing, painting, modeling) are present and acquired. They persist throughout the Upper Paleolithic.

In Chauvet Cave, the combination of graphic and technical expertise, which characterized the important compositions of black paintings during the Aurignacian, along with the very early dates, destabilized some researchers. To summarize, we can say that all adaptations to the medium are present in Chauvet Cave: the drawing incised with the finger tips, with the flint tool on hard surfaces or softer limestone all the way to the use of more complex techniques requiring combined successive gestures (i.e., on the Panneau des Cheveaux). To start, the artist prepared the surface, removing a portion of the fine film of ochre clay that covers the rock surface. Next, the artist set up the figures by species beginning with the rhinoceros, aurochs, and finally the horses. The contours of the animals are first made with charcoal and then the inner surface of silhouettes is hand faded by mixing directly on the wall, charcoal, chalk, and clay remains. The colors obtained thus present nuances that fade from dark gray to light gray and dark brown gray. The next phase is a clipping of figures with a chisel made of flint to clarify the contours and highlight the black animal heads in contrast to the white limestone.

Throughout the Upper Paleolithic, the prehistoric peoples adapted these processes as well on objects as on cave walls and rock shelters. Thus, in the Magdalenian, we see in some regions the development of monumental friezes carved on hard limestone deep inside rock shelters such as Angles-sur-l'Anglin (Vienne) and Cap Blanc (Dordogne). In the Pyrenees, a specialty of clay modeling is evidenced in several neighboring caves such as Le Tuc d'Audoubert in Ariege and Montespan (Haute-Garonne).

According to 14C dating, portable art shortly precedes parietal art but, from the origin, we note that the same patterns (in technique and symbols) govern the works, with no noticeable difference. However, it is principally during the Magdalenian that we find a large diversity of objects, illustrating the range of techniques and supporting media. And as with parietal art, we find variable expertise according to the authors. Here again, it is the combination of criteria that establishes a qualitative difference. A number of objects of portable art stand out because of the choice of material, such as the tooth of a sperm whale sculptured at Mas d'Azil, or in matching of theme and support, such as the self-licking bison at La Madeleine, not to mention the Aurignacian figurines in Germany or the Gravettian female statuettes.

Today we know that graphic techniques and their degree of elaboration do not have a chronological value. We cannot qualify a culture based only on our reflection of the procedural techniques employed in the realization of images, both abstract and figurative. We must also forget the notion of "technical progress" in the sense of an evolution in artistic knowledge that would improve over time. In rock art, evolutionary progress does not exist and we must rethink our paradigms.

Technological Studies in Archaeological Science

Sarah U. Wisseman
Program on Ancient Technologies and Archaeological Materials, Illinois State Archaeological Survey, Prairie Research Institute, University of Illinois at Urbana-Champaign, Champaign, IL, USA

Introduction

Technological studies are concerned with many of the big questions of archaeology: Who made the objects we find? What materials did ancient people use? Where did they obtain their raw materials, and how did they craft pottery, stone tools, buildings, clothing, and other useful items? How did they communicate technological knowledge to each other, and how and where did they trade raw materials and finished objects? Why did people value certain materials and products over others?

The extent to which scholars can answer these questions depends upon the physical evidence left behind (e.g., pottery kilns, potsherds and broken glass vessels, chert debitage, and scraps of preserved textiles), the context of the finds, and the nature of historical information, if any. For example, when dealing with the Roman pottery industry in Italy, France, and Germany, scholars find stamps (Fig. 1) of potters and manufacturers and literary evidence in addition to physical pottery installations for interpretation. In contrast, prehistoric stone pipe and figurine production in North America must be reconstructed from the physical remains (quarry sites and finished objects) alone.

Technological Studies in Archaeological Science, Fig. 1 Manufacturer's stamp on Roman *terra sigillata* (Photo by S. Wisseman, University of Illinois)

Evaluating the evidence is a multidisciplinary endeavor, with teams of specialists collaborating to use appropriate analytical techniques and other approaches such as experimental replication of artifacts to reconstruct early technologies. Success, defined here as arriving at the most likely construction methods and materials used by ancient craftsmen, requires asking the right questions throughout the research process and following a coherent research strategy.

Definition

The study of ancient technologies is really about processes and patterns of human behavior and

about tracing the journey of an object from its beginning as a lump of wet clay or a chunk of obsidian to a finished product used and valued by human beings. This research starts with provenance studies (see separate entry) that examine the question of source (where people found their raw materials) and the trade and exchange of materials and products across the landscape. Technological studies, the primary focus of this entry, reveal material properties and some of the reasons people chose particular materials to fashion into pots, tools, figurines, and cloth, plus the methods they used for fabrication. Such studies are conducted today using a sequence of archaeometric methods (analyzing composition, structure, date, etc., using imaging, microscopic, mineralogical, and chemical techniques). To be cost-effective, most researchers move from macro to micro examination and from simplest techniques (e.g., light microscopy, X-ray radiography) to more complex ones (e.g., neutron activation analysis or inductively coupled plasma spectrometry). Depending on the nature of the research questions posed, it is often useful to perform mineralogical analysis (e.g., petrography, X-ray diffraction) prior to elemental analyses (e.g., X-ray fluorescence) (Emerson et al. 2005).

Understanding the decisions craftsmen made during production (such as how to compensate for bad weather or insufficient fuel during a pottery firing) requires research that goes beyond using instruments for materials analysis. Ethnoarchaeology is the study of living craftsmen who still use traditional practices that can sometimes clarify ancient procedures, and experimental archaeology is the careful replication of artifacts using, as much as possible, materials and methods available to ancient people. Such experiments teach the researchers about the limitations of specific materials, how much skill was required to make tools such as obsidian knives or large ceramic storage jars, and the pitfalls of assuming one knows how something was made just from casual observation or book learning.

For societies who left no written record, detailed examination of the location, layout, and debris of a production site can reveal patterns of behavior that contribute to our understanding of *chaîne opératoire*, or sequence of operations. Social organization and status of craftsmen can sometimes be inferred, although such research is much easier with written or artistic records (e.g., literary sources describing Greek ceramic manufacture and images of potters at work on vases). Cognitive archaeology is the recreation of decision-making and teaching processes used by early craftsmen (e.g., how to judge the correct temperature of an iron forge) through imitation by modern craftsmen. Another area of research is use-wear or use-alteration analysis: the examination of items such as potsherds, cooking pots, or stone tools using magnification, organic residue analysis, and other techniques to determine how artifacts were used and reused over time.

Historical Background

During the early years of archaeometric research, the focus of technological studies was primarily on inorganic materials: clay, metal, and stone. The field was dominated by compositional and authenticity studies using techniques borrowed from chemistry and the physical sciences (various types of microscopy, spectroscopy, radiography, neutron activation analysis, etc.). Early research (in part because some of it was conducted by chemists and physicists rather than archaeologists) focused more on questions of what and how (composition and methods of construction) than on who and why. As archaeologists and anthropologists became increasingly involved in interdisciplinary projects, emphasis shifted to strategies for determining function of artifacts, processes of the craftsmen, and patterns of use and discard.

In the United States, the work of archaeologist Anna O. Shepard (Bishop and Lange 1991) set the stage for careful interdisciplinary studies of ceramics, while physicist Michael Tite's research in Britain applied scientific techniques to the study of composition and structure of ceramics, enamels, glass, stone, and metals. Today, with a host of newer techniques available from the biological sciences, researchers are including organic materials (e.g., textiles, bone, and ivory) in their

quest to reconstruct ancient technologies of every sort and set the materials and methods used by craftsmen into a broader human context.

This broader human context requires expanding our definition of what was important to the people who made the artifacts we study. For example, a craftsman's choice of raw material depends not only upon physical properties (e.g., color, hardness, or behavior when heated) but location relative to production sites and perceived value of a material. Early researchers such as Dean Arnold considered factors such as the weight (of wet clay), the method of transport available, and the amount of manpower required to collect raw materials. However, people's choices of material are also influenced by a desire for exotica, even when the cost of transport of labor is high. For example, researchers in the mid-continental United States have proven that pipestone workers often chose raw material from far away for reasons that are not always clear to modern archaeologists, selecting Minnesota red catlinite over locally available Ohio flint clay (Emerson et al. 2005).

Key Issues and Current Debates

Archaeologists are interdisciplinary scholars out of necessity. Because excavation usually produces only fragmentary physical evidence, archaeologists must be creative about combining approaches to extract the maximum amount of information from potsherds, stone flakes, and scraps of deteriorated textiles. When time and budgets permit, examination of the technologies employed in making a ceramic or glass container, a stone or metal tool, or a piece of cloth often includes the full range of compositional and structural studies (archaeometry), experimental replication, and ethnographic analogy.

Experimental archaeology (see separate section) is one way to illuminate factors in selection or manufacture of artifacts that are not immediately obvious. Although this approach gives the archaeologist firsthand experience of materials and processes, extrapolation of this experience into the past is fraught with difficulties. The researcher needs to understand the processes well enough to identify the variables involved (e.g., choice of raw materials, type of fuel, time, temperature, and atmosphere in a ceramic firing or iron smelting) and then control as many independent variables as possible (Hamilton 2007). If modern materials or tools are employed in the experiments, these additional variables must be taken into account in evaluating the success of the experiments (Claassen 1981). Also, it is easy for the replicator to assume that because he has discovered one way something could be done (e.g., throwing a large vase in three sections), that it was the only way it was done in antiquity. Experimental archaeology helps researchers narrow down possibilities: Finding out that a method of construction is impossible is useful information when it forces them to consider other methods. It also teaches archaeologists the value of hands-on experiments (Buchanan et al. 2016). For example, it becomes clear when making round-bottomed cooking vessels out of clay that using a shallow, already-fired bowl as a mold for the base speeds up the coiling process and thus increases the rate of production of multiple molded-bottom, coiled-body bowls. Similarly, burnishing a pot with a smooth pebble for half an hour in many directions makes classical archaeologists appreciate the value of the slave labor used in ancient Athens.

An example of a thoughtful and well-designed ceramic project is Eric Hostetter's recreation of Lydian terracotta roofing tiles from the site of Sardis in Turkey (Hostetter 1994). Local clays and slips and detailed molds were used for authenticity, but a compromise was reached on the nature of the kilns due to time constraints. After an experimental wood kiln produced reducing conditions that affected the clarity of colors of the finished tiles, electric and gas kilns were employed to achieve a consistent final product that could be displayed to site visitors.

One of the best examples of experimental archaeology is Peter Schmidt's study of ironworking in East Africa. This study successfully blended ethnographic observation of traditional blacksmithing techniques, replication of ancient artifacts, and materials analyses of both

the replicates and the artifacts (Schmidt 1997). In addition to conducting his own experiments with other archaeologists in collaboration with a metallurgist, Schmidt organized several modern smelts that were performed by living Haya craftsmen in Buhaya, Tanzania. He comments, "we needed a method of investigation that exploited the evidence of modern smelts but did not assume that ancient practices were identical to modern ones." This meant the team had to "determine the fingerprints that technological behaviors such as preheating leave behind and then to look for these and other fingerprints in the physical remains of historic or prehistoric smelts" (Schmidt 1997: 129). This approach produced useful information on where slag accumulated in the furnace, temperature ranges, and reuse of some types of slags. Izumi Shimada used a similar combined approach of archaeometric analyses and experimental archaeology to reconstruct the processes and furnace construction used by copper alloy metalworkers at Batán Grande, Peru. Shimada also built a replica pottery kiln at Sícan, Peru, as part of a larger ceramic study (Shimada 2005).

Another example of a metalworking study that combines replication of artifacts with ethnographic observation is Charles Keller's work on African and North American ironworking. While in Africa, Keller served as an apprentice to a blacksmith because he wanted to learn how people learn and how craftsmen communicate valuable technological information nonverbally: by showing or telling rather than using blueprints. This illustrates one of the aspects of cognitive archaeology, trying to understand what a craftsman knows and how he knows it. For example, judging the heat of the forge is often done by color ("red" heat vs. "white" heat), and an apprentice quickly learns by watching someone more experienced about what works and what does not. Or, when making a replica of an eighteenth-century skimmer, a blacksmith holding the historical artifacts but possessing no set of step-by-step instructions must use prior experience and trial and error to achieve the desired result (Keller 1994). Similarly, Raku potters learn that visual cues are the best indicators for when to pull a pot out of the kiln and put it in sawdust: when the glaze looks "like melted ice cream" (Ron Kovatch, *personal communication*).

Other examples of combined approaches (experimental replication, archaeometry, and use-wear analysis) include flintknapping and butchering experiments conducted by scholars such as Nicholas Toth. Toth recreated his own Oldowan tool kit at Koobi Fora, Kenya, learning by experience which rocks and methods (e.g., percussion, anvil) worked best to produce hammerstones, choppers, and scrapers. Then he used his tools to butcher elephants and other animals. Such work informs the archaeologist about which tools are best for which tasks (removing skin, stripping flesh, scraping or cutting bone or plant fibers), and microscopy reveals polishes left by different materials. A more recent study examines hard versus soft percussion traces on chert from central Texas (Buchanan et al. 2016).

When researchers are more concerned with materials and their properties than processes of manufacture, traditional laboratory analysis can answer many questions. Compositional and structural analyses reveal constituents of dyes and pigments in textiles, enamels, ceramic glazes, and glass. Textile chemists such as Kathryn Jakes and Pamela Martoglio have used infrared spectroscopy, scanning electron microscopy (SEM), and other techniques to identify fibers, coatings, and finishes on textiles (Martoglio and Jakes 1990). These methods work particularly well on well-preserved cloth from environments such as Peru or Egypt; SEM has been used to characterize layers of wrappings (Fig. 2) on Egyptian mummies (Proefke et al. 1992). Balms and bitumens used in preserving Egyptian mummies have also been analyzed chemically (Lucejko et al. 2017).

Many scholars (e.g., Tite 1987) have employed surface analytical techniques such as X-ray fluorescence (XRF) to identify the elements (e.g., cobalt for blue, copper for green, iron for red) used to color Roman glass and medieval enamels. Since many extant pieces of ancient glass were isolated from their original contexts and preserved in museum collections, the question of authenticity occurs frequently. For example, the British Museum wondered if the famous Portland Vase,

Technological Studies in Archaeological Science, Fig. 2 SEM of flax fibers from Egyptian mummy wrappings (Photo by M. Raheel, University of Illinois)

Technological Studies in Archaeological Science, Fig. 3 X-ray of Chinese bowl (Photo by R. Keen, University of Illinois)

a spectacular luxury piece with cutout white glass overlaying a blue body, was really Roman or much later, of Renaissance date. Tiny fragments left over from an earlier repair allowed researchers to examine structure and composition using scanning electron microscopy/energy-dispersive spectroscopy (SEM/EDS) and determine that the glass' low potash and magnesia content were consistent with Roman production (Freestone 1991).

Glass was often used in combination with other materials, for example, faience (a ceramic body composed mostly of crushed quartz with an alkaline glaze). A true ceramic glaze is a thin layer of glass bonded to clay, and this layering can be seen easily with an SEM examination. Fluxes (e.g., alkalis, iron oxides) were used to lower the melting point of silica in the glaze material so it would vitrify before the rest of the pot. Other crossover technology is enameling, invented by ancient Egyptians, because it involves melting glass over a metal substrate (Lambert 1997).

The black surface finish of Greek vases confounded archaeometrists and experimental archaeologists for many years. Is it a slip (a suspension of clay in water) or a true glaze? The term for Attic "glaze" is sometimes replaced by "gloss" because it was initially assumed to be a fine suspension of the same clay used for the body of the vase. Greek clay naturally contains illite and iron oxide, minerals that act as fluxes to lower the melting temperature of the surface coating. While some researchers believe that this composition explains the glossy finish so prized by the Athenians and their customers, one study indicates that the surface coating really is a glaze and that the composition was not accidental. Kingery (1991) concluded that the Greeks probably employed special glaze clays and carefully controlled additions of potassium and iron oxide and demonstrated that there is actually a thin layer of glass on the fired surface.

X-ray radiography and other imaging techniques continue to help archaeologists and museum curators answer questions about structure and dating of objects that cannot be destructively sampled. For example, X-rays confirmed the late twelfth century CE date of a Japanese wooden statue and the late tenth century BCE date of a Chinese bronze *gui* bowl. In the former case, the issue was one-piece construction versus multipiece construction, and in the latter case, the X-rays revealed that the Chinese bronze bowl had been cast upside down in a multipiece mold. Also present were bubbles (Fig. 3) in the metal from trapped gas, a feature often present in ancient bronzes but not in modern ones. A pinpoint analysis of the metal (sample taken from the base) showed a leaded bronze with 10–20% tin and no zinc composition consistent with the early date (Vitali et al. 1986). One of the advantages of X-ray technology is that it is less expensive than CT scanning or other advanced medical imaging and is more widely available (at the University of Illinois, researchers have examined everything from Byzantine necklaces to Egyptian mummies at an on-campus veterinary facility).

Current research includes experimental archaeology in new areas, such as ceramic production and cooking methods for North American grains and seeds in periods before European contact. At the Illinois State Archaeological Survey, replicate cooking pots were used to compare two cooking methods used by Woodland peoples: rock boiling (inserting preheated rocks into a grain/water mix) and direct heat (placing the grain-and-water-filled pot directly in the fire) to compare speed of heating and cooking efficiency. The experiments demonstrated that both methods worked for cooking quinoa (a modern descendant of *Chenopodium*, a grain used in the Midwest before about 800 CE) to an edible state in about 20 min and that the necessity of reheating the rocks explained spillover marks, charring, and residues near the lips of the vessels and grit in the gruel (Wisseman 2005).

Colorants used in ancient North American textiles have been examined by comparing fragmentary, barely colored archaeological samples with replicate cloth using close approximations of ancient ingredients: ferrous oxide, ground bloodroot, beef fat, etc. Various types of microscopy, ICP-MS (inductively coupled plasma mass spectrometry), and forensic photography were used to establish a protocol for identification of trace amounts of both inorganic and organic colorants (Baldia and Jakes 2007). This study is a good example of a research project that has broader implications than a single, focused study: It sets up future research by demonstrating a workable selection of processes and a sequence of analyses to achieve useable results.

Future Directions

Archaeologists will continue to use combined approaches (laboratory analysis, ethnographic observation, and experimental replication of artifacts) to extract the maximum information out of fragmentary archaeological materials, especially organics. Larger projects that cut across technologies may become more common. For example, a metalworking study of silver production at Rio Tinto, Spain, during Roman times has produced surprising results that impact analyses of Egyptian mummies. Some of the lead oxides that are by-products of the process form the red pigment *minium*, recently found by a team from the Getty Conservation Institute to be the major colorant in approximately ten Roman-period "red shroud" mummies now in museums around the world. The red pigment was analyzed by inductively coupled plasma time-of-flight mass spectrometry (ICP-TOFMS) and Raman microspectroscopy (Corcoran et al. 2010). This discovery of an exotic and expensive ingredient (in addition to gold leaf) confirms that the "red shroud" mummies were commissioned by well-to-do families in Roman Egypt. The ever-expanding field of mummy studies combines analyses of human remains for health and dietary information with studies of wrappings (e.g., Egyptian linens and Peruvian textiles), resins, amulets, and tools used in embalming procedures and burial rituals.

As the instrumentation available to researchers becomes ever more sophisticated, new possibilities for analysis open up. However, such innovations can be extremely expensive and inaccessible to all but select research teams. One example is synchrotron radiation-based X-ray fluorescence and X-ray diffraction (available at only a few locations in the world such as Argonne National Laboratory), used by Elizabeth Friedman and colleagues at the Illinois Institute of Technology to obtain subsurface data from metal artifacts that cannot be destructively sampled. Other examples include micro-CT scanning for extremely high resolution imaging of tiny samples and next-generation DNA sequencing, currently employed by European researchers to analyze the genome of the Italian Iceman mummy.

One has to keep in mind that the latest techniques are not always required to answer simple questions: For example, distinguishing between brass and bronze requires identifying only three elements: copper plus either tin or zinc. Thus a technique such as energy-dispersive X-ray analysis may be sufficient and a much more cost-effective choice than synchrotron XRF. Similarly, older techniques such as metallography, the microscopic examination of polished sections of metal artifacts, are still extremely useful for

detecting craftsmen's methods, for example, cold working versus repeated heating and cooling of a copper artifact. Appropriate application of archaeometric techniques requires a sequential approach, beginning with the simplest and most cost-effective techniques, with frequent collaborative discussion at each stage to evaluate not only the results but whether and how to proceed with further tests.

Another future trend is combining traditional laboratory-based instrumentation with portable instruments, for example, X-ray fluorescence spectrometers that can rapidly and nondestructively collect data in the field or museum setting. Protocols are still being developed, and the performance of different portable instruments is being compared for accuracy and precision (Shackley 2010).

Despite all the modern instrumentation available today for the study of ancient artifacts and technologies, there are still questions researchers cannot answer, often because archaeological context or other information is missing. For example, in Mississippian archaeology in North America, a mysterious ceramic artifact continues to baffle archaeologists. Called "stumpware," it is a two- or three-legged fired clay piece (Fig. 4) that may be either a funnel for draining lime-treated maize or a firedog used to support cooking pots. Sometimes the stumpware is perforated, but not always in the same place. Some stumpware has a chalky white residue on the exterior, some does not. Could the holes be added by the potter to speed drying time of these thick ceramic pieces? What is the correct function of stumpware, and does it change function over time? Residue analysis, such as that performed by Richard Evershed at Bristol University in the UK to identify embalming resins in Egyptian mummies, may eventually produce an answer.

Technological Studies in Archaeological Science, Fig. 4 Experimental stumpware used as firedogs (Photo by S. Wisseman, University of Illinois)

Finally, the interdisciplinary nature of research on ancient technologies requires more cross-training of archaeologists. While most archaeologists cannot be equally well versed in archaeology and chemistry or the other natural and physical sciences, more than a passing familiarity with available analytical techniques and their advantages and disadvantages is a necessity. Only then can the kind of sustained and fruitful dialogue between specialists of different backgrounds produce results that help scholars successfully interpret the technological behavior of past cultures.

Television and Archaeology: Views from the UK and Beyond

Greg Bailey
Department of Archaeology and Anthropology, University of Bristol, Bristol, UK

Introduction

For millions of people, their primary engagement with archaeology is through the now-traditional medium of linear broadcast television (Merriman 1991: 119–120; Holtorf 2007: 52–54). Though undoubtedly challenged by newer ubiquitous information technologies with rapidly evolving modes of reception, after more than half a century, this largely remains the case (Pokotylo and Guppy 1999; Payton 2002; Clack and Brittain 2007: 14). However, any archaeological message on any media platform is generated, transmitted, and received within a particular sociocultural technological environment. Viewed as material culture, the historical, economic, political, and ideological context of broadcasting might itself be considered as an anthropological or indeed archaeological meta-narrative (see Huhtamo and Parrika 2011).

Furthermore, archaeology, a project almost wholly funded directly or indirectly from the public purse, is granted singular public trust (Hodder 1987: 166). Yet, the TV broadcasts of the twentieth century's economically developed countries –

those that created mass audiences for electronic media – inevitably reflected particular geo-historical views of both scientific method and world culture. This context for the establishment of many of the most enduring themes, formats, and common tropes of TV archaeology must be pertinent to any understanding of a dynamic interacting relationship.

As a subject, archaeology perfectly answered the call of Lord Reith – founder and first director general of the British Broadcasting Corporation (1927) – to "educate, inform and entertain." Accordingly, the decades from the early 1950s – especially in the United Kingdom with this public service remit for its publically funded broadcaster – generated a recognizable genre for TV archaeology. If many of the formats then created have survived because they are somehow fit for purpose, we might still ask if or how this purpose has changed. TV archaeology could certainly be said to have consolidated, if not originated, new areas of research, to have widened public interest and involved new communities in the archaeological process. Nevertheless, we might consider that in the intervening years, beyond methodological advance, archaeological thinking has also evolved.

Definition

Archaeology, ancient story
Television, far sight
Broadcast, to scatter seed

1. Single TV program or series whose content deals with archaeological research or opinion or the historiography of archaeology or otherwise substantially relies on archaeological data or theory to inform a broadcast narrative.
2. Single TV program or series whose content contains archaeological research or opinion or the historiography of archaeology or otherwise deals with or utilizes archaeological data or theory to form some part of a broadcast narrative.
3. Archaeologies of broadcast media, broadcast networks, or associated television technologies.

Historical Background

Archaeology first impacted a popular television audience as that most recognizable and enduring TV staple: the panel game. Broadcast from Philadelphia USA, the long-running Peabody Award-winning network quiz show *What in the World*? ran from 1951 to 1965 (WCAU TV; CBS). The (necessarily) studio-based series saw a distinguished panel of experts asked to identify artifacts from the worldwide collection of the *University of Pennsylvania Museum of Archaeology and Anthropology*. Clearly offered as entertainment – over opening titles, the camera tracked through swirling mist to reveal the first mystery object while a portentous commentator "your offscreen voice," identified the item for viewers – the show did not lack academic substance. The Penn Museum acted as coproducer, and its director, Dr. Froelich Rainey, fronted each program as on-screen host. Eminent archaeologists and anthropologists (and in episode four, celebrity guest, actor Vincent Price) readily tested their expertise – and reputation – while recognizing relics on live TV before viewing millions.

Nor was jeopardy lacking in the UK's more staid response though, BBC's *Animal Vegetable Mineral* (1952–1959) strived less for dramatic effect. Gone were dry-ice, offscreen voices and celebrity guests, or indeed the freedom of panelists to stroll across the studio to a rotating plinth and the article in question. Artifacts were now handed to panelists sat solidly behind their stage-set desk. Whether different production values were due to institutional reticence, seriousness of intent or less developed studio techniques, AVM's guests, and mystery artifacts – picked from the British Museum, regional galleries, and university collections – were as distinguished as those of its American counterpart.

Leading archaeologists of their day, Cambridge professor, editor of the Antiquity journal, and question-master Glyn Daniel, Mortimer

Wheeler, Gordon Childe, and Jacquetta Hawkes all played the game. These luminaries, whose collective scholarly publication was unequaled, evidently understood this popular entertainment as a logical extension of their normal educational remit. Just how popular may be judged by Mortimer Wheeler and Glyn Daniel being voted TV Personality of the Year in two successive years (1954, 1955). While following transmissions of AVM, "libraries found that neglected shelves of archaeological books were suddenly empty" (Paul Johnstone: Times obituary of 17.3.1976).

The runaway success of *Animal Vegetable Mineral* established archaeology as a television fixture, and its producers proceeded to set an agenda that determined our views.

Paul Johnstone, Mary Adams "Head of Talks" (factual broadcasting), and then new recruit, assistant producer David Attenborough, helped establish the language and syntax of TV archaeology with a genre which (exceptionally) has never left British television screens.

With *Buried Treasure* (1954–1958), the production team shifted the archaeological question from "what" to "how." If inspired by John Lubbock and Augustus Pitt Rivers, the series introduced experimental archaeology to television. So, Mortimer Wheeler duly grimaced at tasting the last meal of Tollund Man as identified from remains in the gut of the Iron Age bog body. Viewers saw how a prehistoric round house was built and – an enduring TV fascination – how the builders of Stonehenge might have transported 60 blue dolerite stones some two hundred miles from the Preseli Hills of Pembrokeshire to Salisbury Plain.

A defining moment came in 1965 when David Attenborough abandoned his doctorate in social anthropology to return to television as controller of a new color TV channel. Arriving with a mission, Attenborough promptly invited Johnstone, his former boss, to create a unique department dedicated to archaeology and history.

This confluence of a ready audience, the personal support of management within a well-resourced public institution at a turbulent yet broadly progressive historical moment coincided with emergent technologies (for Actor Network Theory see Latour 1993). Development in the design of the Arriflex BL provided a lighter, silent camera that could be handheld, while faster 16 mm colour film stocks allowed for minimal lighting. These together with the introduction of portable Nagra III magnetic tape recorders and an ability to record synchronous sound and picture meant Johnstone's specialist unit could economically film the process as well as the product of archaeology.

Chronicle, BBC 2's flagship series, ran from 1966 to 1991, coinciding with formative years for archaeology. Again, practitioners at the leading edge of archaeology including Colin Renfrew and Barry Cunliffe played their part, but it was the subject matter of *Chronicle* that did much to widen the scope and ambition of archaeological discourse in Britain.

While *Chronicle* was anything but parochial, frequently traveling worldwide to film iconic sites, the series also acted locally as an early forum for community archaeology. In 1970, *Chronicle* helped mobilize amateur enthusiasts to champion nineteenth- and twentieth-century industrial archaeology – a discipline not yet universally accepted by professional archaeologists. Local societies, founded to conserve particular factories or machines, were invited to compete in order to feature in a special series of *Chronicle* films. Consequently, film segments on the restoration of an abandoned needle-making factory at Redditch, research into the history of Manx lead mines, the Faversham gunpowder mill, and salvaging of steam engines from nineteenth-century cotton mills were duly transmitted.

Likewise, Johnstone's enthusiasm for maritime archaeology provided a recurring theme, which helped establish another academic subdiscipline. This saw ever more ambitious archaeological experiment, including the building and sea trial of a 21 foot long replica Bronze Age skin boat. Chronicle also contributed to some of the most daunting industrial/maritime rescue archaeology ever undertaken.

The 1970 return of Isambard Kingdom Brunel's iron steamship SS Great Britain to Bristol and her surprisingly intact construction dock 127 years to the day after the vessel's outward

voyage became headline news. Towed from her ignominious berth as a guano-storing hulk ship in the Falkland Islands/Malvinas, the 69-day trip was filmed by onboard Chronicle producer Ray Sutcliffe. Two years in the making, the program on the SS Great Britain (now refurbished and one of Bristol's favorite tourist attractions) had been a major investment but by no means *Chronicle*'s greatest.

From 1968 to 1970, the BBC funded three seasons of excavation at Silbury Hill, Wiltshire Richard Atkinson's investigations into the reputedly largest prehistoric earthwork in Europe meant tunneling through chalk and clay to the core of the 37 m high, late Neolithic mound. This involved not just large-scale archaeology and specialized mine engineering but for the broadcaster, an ongoing commitment of resources. To supplement filming over 4 years, outside broadcast (OB) units – newly designed for BBC 2's sports coverage – with their mobile control rooms, live-feed transmitters, lights, generator trucks, camera and sound crews, electricians, riggers and drivers, were regularly commandeered for live updates on the excavation's progress. Although for some journalists not an unqualified success – few artifacts were found and no King Sil on a golden horse – *Chronicle*'s dedication to the Silbury Hill project speaks volumes for how former British television executives valued archaeology.

It might seem extraordinary that archaeology could rank with moon landings, state occasions, or international sporting fixtures as landmark television, but in 1970 and again 10 years later with the raising of the Tudor battleship Mary Rose, archaeology was presented as rolling news and live TV event.

Key Issues

Formatting Archaeology

Television has long held a special place in British culture. Moreover, in the four last decades of the century, a protected UK broadcasting industry could encourage bold experiment allowing controversy or even failure. In this environment, a blueprint for TV archaeology was formulated and much since could be thought variations on a theme. Considering 590 UK programs broadcast between 1999 and 2002 during its millennial "golden age," Karol Kulik identified six distinct categories of TV archaeology (2006: 75–88).

Time Team now in its final season (broadcast 1994–2013) exemplifies the first of these: archaeology as process or "backstage." Despite an emphasis on professional and technological know-how, the Channel 4 format retained an element of jeopardy inherited from its game show origin: the arbitrary time limit of a three 3-day dig. Featuring a different location every week, each show targets a particular period or site type. Archaeological questions are posed and *Time Team* viewers follow the progress of excavation and site interpretation and are offered insight into practical fieldwork. Realistically enough, professional disagreement is not uncommon, and results can be unpredictable. Widely accepted as the market leader with consistent audience brand loyalty, the process-driven "behind-the-scenes" approach of *Time Team* along with protagonists Mick Aston (until 2012) and Phil Harding, for many, came to define TV archaeology.

Particularly popular with cable and satellite networks, Kulik's "detective" format poses a mystery or riddle that – it is proposed – archaeology alone can solve. On-screen archaeologists may offer and evaluate evidence, but the detective story narrative begs solution. Unlike programs focusing on the investigative process, here a script is prewritten to reach a foregone conclusion. The question asked may be more or less valid in presupposing that any single meaningful answer is possible. Its underlying premise – Atlantis, ancient aliens, "lost" civilizations – might also be questionable.

Less overtly sensational, the "expository" model follows John Grierson's documentary style (see Winston 1995). Taking a seriously minded, educational overview, typically of large-scale cultural phenomena, an illustrated lecture is delivered by omniscient "voice-of-god" commentary, which links authoritative screened interviews.

An increasingly ubiquitous format, the "essay" differs from the above in that it is narrated by an

on-screen presenter offering a (supposedly) personal point of view on some general archaeological theme. If expert opinion is sought, the presenter asks the questions and – despite taking a greater or lesser part in the scriptwriting – records voice-over commentary. It is not always apparent whose views we really hear.

Kulik describes programs that consist wholly of archaeological experiment as "how-to." These may reconstruct buildings or lifeways, recreate ancient technologies, or solve an ancient engineering conundrum. BBC's *Living in the Past* (1978) in which volunteer families lived for a year in a simulated Iron Age Village is claimed to have invented "reality TV." This was the prototype for the German *Steinzeit: Das Experiment* (Stone Age: The Experiment SWR/ARD 2007), the biggest TV archaeology event ever. The climactic episode, which saw two reenactors leave their newly built Neolithic pile dwelling on Lake Constance to retrace Otzi's last journey across the Alps, reached a truly astonishing 30.4 million viewers over two consecutive evenings (Bailey et al. 2009).

Lastly, "reconstruction" refers to a TV narrative, which based on archaeological research relies on actors with appropriate costume and sets to dramatize some past event(s). Particularly popular in non-Anglophone continental Europe and while costly, being commentary driven, these lend themselves to language "versioning," thus facilitating resale and universal distribution.

Marketing Archaeology

Commoditization in a globalized television market have seen international coproduction become the norm. These products are characterized by periodic narrative cliff-hangers for the ready insertion of frequent commercial breaks. Meanwhile, an accompanying tendency for multinational corporations to acquire medium sized independent production companies whose chief asset is the exploitation of existing intellectual property – TV format rights – will favor homogenization over experiment and uneconomic risk (Kretschmer et al. 2009).

While game show and "reality television" – the most commercial international formats – have historical associations with TV archaeology, these are perhaps less likely to shape its future. Rather, "pop" archaeology's proven themes of pyramids, mummies, skeletons, treasure, unsolved mystery, or notions of heritage and cultural identity presented as high-gloss factual television may endure as readily tradable commodities.

Since Kulik developed her typology, few archaeology programs defy niche categorization. Among these, BBC 1's costly ill-fated drama series *Bonekickers*, which had a fictionalized university archaeology department as setting for a high-concept adventure serial, is memorable. A second series was not commissioned (Bailey et al. 2009).

Although informed and refreshingly different, the guerrilla-film approach and montage editing of Canadian Simcha Jacobovici's *Naked Archaeologist* (Vision TV) challenged orthodox ideas of both television and archaeology. The show's mischievous humor made it particularly difficult for European terrestrial broadcasters to understand or schedule.

However, up to a third of all Swedish viewers regularly watched the series *Utgrävarna* (Excavators SVT 2005). The reflexive "post-memory work" of archaeologist Jonna Ulin demonstrated that screening views not just of, but from, the subaltern could make popular TV. Inspired by the excavation of her own grandmother's childhood home, Ulin based each episode on an abandoned contemporary site and the memories of neighbors, family photograph albums, and the discarded or treasured things of everyday life – archaeology as evocation.

Some other TV programs dealing with material culture or heritage are not explicitly badged as archaeology (see *Saving Britain's Past* BBC 2; 2010) while magazine formats may include just some archaeological content (*Coast* BBC 2; 2005 to present).

Discussion

Archaeology gripped public imagination long before any dominant TV narrative. Best-selling books, accounts of excavation, fabulous finds, and forgotten civilizations from Egypt or the Near East were popular since at least the 1920s.

For their archaeologist authors, such publications needed only to adapt and edit the familiar conventions of report or scholarly monograph with explanatory text and discussion illustrated by drawings and photographs. In the first half of the twentieth century, archaeologists could transmit their message directly.

With the emergence of TV as focus of family life, as electronic hearth in the living rooms of the postwar western world, such communication became a more collaborative venture. Millions, who perhaps rarely explored museums or pored over books on great excavations or paused to think about how or why one might relate to abandoned things, found analogous enquiry transmitted unbidden into their home. If a historic opportunity for those who considered public communication a central disciplinary concern, archaeologists necessarily approached the small screen on its own terms.

It is the responsibility of the television producer(s) to oversee a protracted, creative, technical process and who is contracted to manage and deliver programs to a licensed broadcast network with access to a complex telecommunications infrastructure. As such, the lead author or final editor of a TV show could rarely if ever be a working archaeologist. Given this, any productive collaboration depends not just on trust and acceptance of different cultures, traditions, and professional imperatives but how producer and archaeologist each *imagine* medium and message. To what extent archaeology is visualized as method, practice, sanctioned treasure hunt, or platform for ideas, or again, television approached as powerful but superficial medium, animated textbook, opportunity for reflexive exercise, or vehicle for original research, determines the outcome.

Any dissonance in academic restraint and lively popular storytelling might be resolved – or in skillful hands even harnessed to creative effect – if the nature of a particular narrative is mutually agreed and understood.

Today, the early adopters of mass media in those same affluent countries broadcast to an increasingly skeptical public. However, for their audiences, which have since come to question many traditional secular or religious authorities, faith in the status of archaeological proof – as seen on TV – seems to be unshaken. This may have much to do with different perceptions of archaeology and what – in the minds of broadcasters – archaeology offers television viewers.

Thus, in what we are constantly reminded is a visual medium, image needs description rather than critique. In this view archaeology is self-explanatory, an end in itself requiring no further justification or contextualization. Seeing is believing, while TV archaeology avoids overt theory and the politics of archaeology remain subliminal.

If any such uncritical accounts – however well intentioned – act as an authoritative source for founding mythologies or help establish dubious notions of identity, this is problematic. The possibility of inferring any special historical or territorial claim from archaeological research must make its popular representation a central disciplinary concern. Or indeed of general concern, for as Stephanie Moser notes, disciplinary boundaries are permeable, and a continuum exists between the interacting spheres of archaeological practice, representations of archaeology, and its public reception (Moser 2004: 262–283; also see Shanks 2007: 274).

Public Image, Public Effect

While a direct causal relationship between TV archaeology and active participation in heritage or archaeological pursuits is difficult to prove (for a critique of the media "effects model," see Gauntlett 1998), limited data suggest a strong correlation. In the UK, negative evidence, at least, suggests that preexisting self-selection was instrumental, in that ethnic minorities have very largely chosen not to watch "heritage" themed TV (Piccini 2006), or join the archaeological profession in any capacity (Aitchison and Edwards 2008: 11, 14), or apply to study archaeology at university (UCAS figures 1995–2006).

Yet, sampling of prospective candidates and first-year undergraduate students at archaeology departments in Bristol and Southampton overwhelmingly suggests previous interest in televised

archaeology (Bailey 2007–11, unpublished). For this generation, *Time Team*, frequently watched in the company of at least one parent, was most often cited as favored viewing. So these partial data might suggest the show's consolidation of archaeology's long-standing appeal within the family rather than as initial inspiration.

English Heritage statistics too confirm family background as highly influential but also indicate that intensive generalised TV viewing (over 5 h a day) reduced this groups probability of visits to "historic attractions" by up to 13%, while for viewers of "heritage TV," including archaeology, visits to "monuments, castles, and ruins" increased by a significant 12% (Wineinger 2011).

It seems that rather than simple cause and effect, TV archaeology relates to other archaeologies as part of a network of interdependent practices, a key relationship that helps shape a collective cultural consciousness.

Tello, Julio C.

César Astuhuamán
Universidad Nacional Mayor de San Marcos, Lima, Peru

In the beginning of the twentieth century, Peruvian archaeology was emerging within a hostile context: there was a lack of any proper institutional organization, absence of indigenous scholars, depredation of archaeological sites, and deficiency of state support in both economic and legal terms. In addition, a weak national identity caused the segregation of pre-Hispanic history. In these circumstances, Julio César Tello Rojas emerged and became a prominent national icon, an international anthropologist, and the father of Peruvian archaeology.

Tello was born in Huarochirí (highlands of Lima) on April 11th of 1880. He was given financial assistance from his family to go to college in Lima, where he was further supported by Ricardo Palma. Likewise, working in the national library enabled him to attend to San Marcos University, where he studied medicine. In 1908 he submitted his thesis on the antiquity of syphilis in Peru suggesting that it was ancient syphilis which prompted the need for trepanation evident on many pre-Columbian skulls. This was a pioneering interdisciplinary study, which was also expressed in his later work *Wiracocha*, where Tello creatively draws from ethnohistory, linguistics, medicine, and anthropology in order to interpret the archaeological remains. The research questions of his thesis shed light on the origins of Andean civilization. Exploring the younger Tello allows to understand the older Tello, his changes and continuities.

Ancient trepanation and skull deformation were topics that continued to fascinate Tello and to which he later returned for his doctoral thesis submitted in 1918 to San Marcos University. In 1909 Tello was given a grant by the Peruvian government for further study, and rather than continue his career in medicine, he chose to attend to Harvard University to study anthropology. In 1911 and with another grant from the Peruvian government, Tello traveled to Britain, where he gave a presentation on pre-Hispanic trepanation at the 18th Congress of Americanists in London, and he also married Mabel Cheesman in 1912.

Tello participated in early expeditions to collect materials for American museums: 1913 (Lima Region), 1915 (Peruvian South Coast), and 1916 (Harvard Peruvian Expedition to Northern Peru). During his participation in these expeditions, Tello learned directive skills that will provide him with the experience and maturity to direct great projects as Chavín de Huantar (1919).

By 1913 Tello proposed the creation of the National Museum of Archaeology in his report "The Present and Future of the National Museum." In this work Tello challenges the dominant vision of Peruvian European elite in the historical explanation of ancient Peru. Tello promoted an indigenous and anthropological view of the Andean past. Pursuing his ideals, he created the Museum of Anthropology and Archaeology, taught the first courses of archaeology at San Marcos University, worked as editor of anthropological journals, and participated in national and international academic meetings. Thus, Tello notably improved Peruvian archaeology and our vision of the Andean past in both national and international contexts and became an inspirational figure for the Peruvian *indigenismo* movement.

Tello was also engaged in politics and was strongly linked to presidents Billinghurst, Leguía, and Benavides. He even worked as Deputy of the National Congress during Leguía's government (1919–1930). The interplay between archaeology and politics, past and present, was a constant in Tello's praxis; thus, he gained support to develop his anthropological projects from national and foreign politicians.

Some of Tello's major contributions for the development of Andean archaeology were related to chronology (before radiocarbon dates), recording archaeological sites, artefactual analysis, and the importance of the relationship between historic process and geographical areas. Tello proposed a chronological sequence for the Central Andes in *Antiguo Perú: Primera Época* (Tello 1929) and *Origen y desarrollo de las*

civilizaciones prehistóricas andinas (Tello 1942), he described and illustrated – with maps and charts – the spatial and chronological distribution of Andean cultures and civilizations in the drainage basins of the region. Currently, his field notes are being published by San Marcos University.

Tello's proposal for the Andean chronological sequence was based on four stages of civilization developed on different regions: Andes Orientales, Andes Occidentales, Litoral del Pacífico, and Tahuantinsuyu (Tello 1942: 111–126).

In a time when the origins of Peruvian civilization were linked to Mesoamerica, Tello (1921, 1942) proposed the autochthonous emergence of the Andean civilization and the existence of a "mother culture" (Tello and Mejía 1960). This is a theoretical legacy for Peruvian archaeology.

Tello also explored the spatial distribution of provincial centers during the Inca expansion in the drainage basins of the Central Andes. He summarized and pictured his proposal in two maps, "Peru Precolombino, III Epoca, Tawantinsuyu" (Tello 1930) and "Las principales naciones incorporadas al Tahuantinsuyu" (Tello 1942). The latter was mainly focused on locating the ethnic groups dominated by the Inca. Tello argued that the main feature of the Inca Empire was that the great cities distributed along the Central Andes had similar settlement planning and were built with rocks and adobe (Tello 1942: 93–108). Tello stated that the Inca civilization was the last stage of a long historical development; it was a confederation of nations linked by strong and traditional ties which were harmoniously coordinated by the Inca nation (Tello 1942).

Tello's archaeological interpretations were partially influenced by the increasing Peruvian nationalism, but this can be better understood in the historical context of his proposals about spatial, cultural, and chronological divisions that were elaborated to explain pre-Hispanic historical processes in the Central Andes. Tello's works, discourses, and praxes placed the pre-Hispanic societies in the center of the historical explanation, empowered contemporary Andean societies, and contributed to build a Peruvian national identity.

On June 3rd of 1947, after a long disease, Tello passed away and was buried in the National Museum of Anthropology and Archaeology. The day of his birthday was proclaimed the Peruvian Archaeologist's day.

Tells in Archaeology

Wendy Matthews
Department of Archaeology, School of Human and Environmental Sciences, University of Reading, Reading, UK

Introduction and Definition

Archaeological mounds form when activities and settlement were conducted at a site over time and

sediment and material accumulation rates exceed those of truncation or erosion. In Southwest Asia an archaeological mound is called a "tell" in Arabic, "tepe" or "chogha" in Farsi, and "höyük" in Turkish. In the ancient Near East, mounds may vary in size from c. 30 m to 1 km in diameter and in height from c. 1 to >43 m (Fig. 1). The archaeological investigation of these mounds presents a range of major challenges: (1) low mounds and the bases of mounds may be masked by several meters of sediments from rivers, hill-wash, or erosion; (2) early levels may be buried below many meters of later settlement and difficult to access; (3) materials may be recycled and redeposited throughout a mound by successive construction and digging of pits or graves, for example; (4) with shifting settlement patterns and variations in construction and leveling, mounds are not uniform "layer cakes" and include truncated or eroded areas; and (5) mounds may represent only one aspect of settlement patterns and strategies, but may be overrepresented in field investigations due to their predominance in the landscape. Mound sites nevertheless often provide rich sequences of well-preserved deposits and many aspects of ecological and social strategies. The examples below are largely from interdisciplinary excavations in Syria.

Key Issues/Current Debates/Future Directions/Examples

Satellite imagery, aerial photography, surface survey, and *geomorphology* have been applied to study the extensive networks and landscapes of large and small sites in the steppe regions of northern Syria, as in the Tell Hamoukar survey (Ur 2010). Here, satellite pictures showed that many tell sites were connected by radial routeways that formed from at least the fourth millennium BCE. Surveys of artifacts, notably pottery, on large and small tell sites, have identified several major peaks in settlement in northern Syria, notably in the mid-late fourth and mid-third millennia BCE, as well as decline, as in the late third millennium BCE during a period of climatic stress, when many large sites were partially abandoned and smaller sites along watercourses were frequented (Wilkinson 2003).

At the scale of individual tell sites, specific periods and types of activity areas have been *evaluated* by close integration of studies of *surface materials* and tell *geomorphology* and *topography* to detect in situ materials in actively eroding areas of mounds. By these methods, previously unexplored and otherwise deeply buried levels from the Ninevite five periods of the early third millennium BCE were excavated at several points around the large mound of Tell Brak, including a small temple/shrine (Fig. 1; Matthews 2003).

Rapid extensive investigation of subsurface features and buildings at tell sites have been very effectively investigated by *geophysics*, as in the recovery of the whole plan of the lower town of the mid-third millennium BCE at Chuera, by *surface scraping*, as at Tell Brak (Matthews 2003), and by *mechanized sweeping*, as at Sheikh Hamad. Walls, features, and floors were often constructed from compressed mud or mud brick and mud plaster. These may show clearly (Fig. 2), but when the fill around them is from similar materials (e.g., from leveling or collapse), they may be more difficult to detect.

The definition of walls and surfaces depends on close observation of the characteristics of deposits and interfaces between layers. The edges of walls can be identified in plan by shaving clean the excavation surface with a hoe or trowel if deposits are moist or by cleaning briskly with a large brush if dry. During excavation, wall and surface faces can be detected by looking and feeling for changes in composition, texture, structure, and fractures along edges or surfaces using a small pick or trowel. Section profiles provide an important *reflexive* record of deposits and features as they are being excavated and should be kept clean (an artist's palette knife is particularly effective) and regularly examined at the edge of trenches or in strategic sections through features and floors. Records are made of structures (buildings), features (walls, hearths), and layers (floor deposits or fills) using digital photography and videos, high-precision architectural survey, plans, section drawings, and written descriptions.

Tells in Archaeology, Fig. 1 Aerial view of excavations and large monumental buildings at Tell Brak, Syria (43 m high, >800 m long, and 40 ha in size). (After Gerster 2003: Fig. 32)

Tells in Archaeology, Fig. 2 Micro-history of a large walled building and surfaces in a street in area HS3, Tell Brak. Location of blocks for microscopic analysis of sequences also shown

The detailed histories of buildings and settlements have also been studied using techniques for analyzing sequences of floors and activity residues, such as *microstratigraphy* and *micromorphology* (microscopic analysis of layer content and sequences) (Fig. 2; Matthews 2003) and *chemical mapping* (as at Çatalhöyük, Turkey). An increasing range of analyses can be conducted in the field. These include portable X-ray fluorescence to characterize architectural and artifactual materials and activity residues (e.g., high phosphorus concentrations), and microscopic analysis of spot samples of sediment to look for plant phytoliths and dung spherulites to identify animal pens, for example, and thereby inform excavation and sampling strategies (as conducted by the Central Zagros Archaeological Project (http://www.czap.org/)). Exemplary interdisciplinary scientific analyses of spectacular burials at the mid-second millennium BCE site of Qatna, in western Syria, include study of the human remains, artifact materials and technology, and organic residues within the vessels.

Large-scale long-term research excavations at major tell sites are providing major insights into the diverse structure and histories of these settlements including changing social and political organization, economies, and ritual practices, which are becoming increasingly well defined. Examples in Syria, from regional and local centers, include Ebla, Tell Brak (Oates et al. 2001), and Tell Beydar in the third millennium; Tell Leilan in the second millennium BCE; and Sheikh Hamad in the first millennium BCE. Rescue excavations are also contributing to research. For example, the integration of the archaeobotanical and archaeozoological data

from rescue excavations at several small sites along the Khabur river, sampled prior to their flooding by dam waters, has enabled study of major developments in the intensification of agriculture in the fifth-third millennia BCE in this region (Fortin and Aurenche 1998).

The results from many of these projects have been closely integrated in regional conferences, workshops, and major chronological and environmental research projects and frameworks, such as ARCANE (http://www.arcane.uni-tuebingen.de), and extensively published. Some sites have been conserved and presented for public display and dissemination in situ, within museums and on websites.

Tenochtitlan (Aztec): Geography and Culture

Lilia Lizama Aranda
Manejo Cultural Research Center, Faculty of Anthropological Sciences, University of Quintana Roo, Puerto Morelos, Quintana Roo, Mexico

The terms "geography" and "culture" for the people of Tenochtitlan entail the development of a culture whose diversity and richness in ecosystems, species, and genes is derived from climatic, geologic, and relief conditions. Developing an identity according to the resources in which it takes place therefore is an argument based on interpretation of a culture on the basis of concepts and ideas that may belong to another culture being used to interpret this one. Therefore, the names used by authors – such as gods, empires, or nobility – might be not right. Nonetheless, authors have strived to become quite objective for their interpretations, yet have to rely on this use. We owe the peoples of this valley, the geography, and thereby their gods, for leaving behind a legacy to be learned, yet to be understood (aside from simple concepts), and yet to be compared with one another.

Introduction

According to Flores Garcia, consideration of the Aztec culture – when it is about power and law – should not be viewed within the appreciation of what Morgan calls savagery, barbarism, and civilization.

Important aspects to consider, and based on the judicial system at a global level – a point made by Flores Garcia (1980: 62) – are high maintenance of social order, good costumes, respect for legal institutions, and education. These depict a system, evidenced by academics for decades, held to a high level of a sense of justice, impartiality, and equity for those chartered with administering it in those times.

To understand part by part what Tenochtitlan was, we will look first into knowing how Tenochtitlan was initiated and how it was organized. The geography of this culture entails an intrinsic clue to its development. At the very top of the gods who occupied the most prominent space within the temple of their city was Huitzilopochtli. He represented the solar cult, but in this city, there was a long list of gods who were recognized by the people who built it and lived there. His pyramid was built as a dual pyramid and had a shrine in the south of the site (*huitzil* means "hummingbird," in relation to the sun at birth – "tender like a hummingbird"), and another for a god named Tlaloc was built in the north; he rose from a spring and represented legitimacy and antiquity, as well as rain, lightening, fertility, and earth. According to Miller and Taube (1993: 93), Tlaloc welcomed Huitzilopochtli when the Aztecs fled the mainland and went to the island in the middle of Lake Texcoco in 1345. Between these two gods was born the concept of war in the shape of fire and water, but it was under Huizilopochtli (hummingbird of the south) started the human sacrifice within the war (the "hummingbird of the south" as symbol of bravery, perseverance, and patience, which helped them find this place), while Tlaloc was known as "the provider."

Authors suggest (Miller and Taube 1993: 25) that this tribute of human sacrifice became unfavorable at the time of the Spanish conquest, as the Aztecs never imagined this practice of taking enemies from their surroundings to sacrifice through their special type of war would take a toll at end of their culture.

It is possible that since these times the Aztecs or the people who had arrived at Aztlán were traditionally practicing the *xochiyaoyotl*, or the "flowery war."

As Miller and Taube (1993: 42) have pointed out, the name Aztec become popularized by William Prescott in his book *Conquest of Mexico*. It had been introduced earlier by Alexander von Humboldt in the nineteenth century; he gave the meaning of "people of Aztlán." Aztlán means "place of whiteness." But these people rarely called themselves; by this name; instead, they called themselves Mexica, or sometimes Culhua Mexica, to denote their linkage with Culhuacan as old Toltec lineages. The lineages are thought to be understood according to Romero Vargas Yturbide (1959). Individuals being representatives or administrators were chosen according to the day of birth and merits such as honesty, responsibility, integrity, knowledge, and bravery, in a way that any member of the society could become governor, not only the sons of representatives in turn. These were merits that guided the Mexica to find the appropriate place, under the ecologic and geographic conditions, for the development of their culture. This being said, pilgrimage guides were identified according to certain elements of identity such as the level of knowledge and the day of birth. Pilgrims were depicted carrying a sack, which represented their responsibility, and Chimalma, as their guide, was the government representative. Lastly, their justice system has no parallel in our present world, being based on the abovementioned virtues yet obscure to our understanding, based on the happiness of others rather than of oneself (Flores Garcia 1980).
